The information contained herein is for informational purposes only, and is subject to change without notice. While every precaution has been taken in the preparation of this document, it may contain technical inaccuracies, omissions and typographical errors, and AMD is under no obligation to update or otherwise correct this information. Advanced Micro Devices, Inc. makes no representations or warranties with respect to the accuracy or completeness of the contents of this document, and assumes no liability of any kind, including the implied warranties of noninfringement, merchantability or fitness for particular purposes, with respect to the operation or use of AMD hardware, software or other products described herein. No license, including implied or arising by estoppel, to any intellectual property rights is granted by this document. Terms and limitations applicable to the purchase or use of AMD's products are as set forth in a signed agreement between the parties or in AMD's Standard Terms and Conditions of Sale.

### Trademarks

AMD, the AMD Arrow logo, and combinations thereof are trademarks of Advanced Micro Devices, Inc. Other product names used in this publication are for identification purposes only and may be trademarks of their respective companies.

HDMI is a trademark of HDMI Licensing, LLC.

HyperTransport is a licensed trademark of the HyperTransport Technology Consortium.

Microsoft is a registered trademark of Microsoft Corporation.

MMX is a trademark of Intel Corporation.

PCI Express and PCIe are registered trademarks of PCI-Special Interest Group (PCI-SIG).

### Dolby Laboratories, Inc.

Manufactured under license from Dolby Laboratories.

### Rovi Corporation

This device is protected by U.S. patents and other intellectual property rights. The use of Rovi Corporation's copy protection technology in the device must be authorized by Rovi Corporation and is intended for home and other limited pay-per-view uses only, unless otherwise authorized in writing by Rovi Corporation.

Reverse engineering or disassembly is prohibited.

USE OF THIS PRODUCT IN ANY MANNER THAT COMPLIES WITH THE MPEG ACTUAL OR DE FACTO VIDEO AND/OR AUDIO STANDARDS IS EXPRESSLY PROHIBITED WITHOUT ALL NECESSARY LICENSES UNDER APPLICABLE PATENTS. SUCH LICENSES MAY BE ACQUIRED FROM VARIOUS THIRD PARTIES INCLUDING, BUT NOT LIMITED TO, IN THE MPEG PATENT PORTFOLIO, WHICH LICENSE IS AVAILABLE FROM MPEG LA, L.L.C., 6312 S. FIDDLERS GREEN CIRCLE, SUITE 400E, GREENWOOD VILLAGE, COLORADO 80111.

# Table of Contents

<b>1</b>	<b>Overview</b>	<b>18</b>
1.1	Intended Audience	18
1.2	Reference Documents	18
1.3	Conventions	18
1.3.1	Numbering	18
1.3.2	Arithmetic And Logical Operators	19
1.3.3	Operator Precedence and Associativity	20
1.4	Definitions	20
1.5	Changes Between Revisions and Product Variations	25
1.5.1	Revision Conventions	25
1.5.2	Major Changes	26
1.5.2.1	Major Changes to Core/NB Performance Counters	27
<b>2</b>	<b>Functional Description</b>	<b>28</b>
2.1	Processor Overview	28
2.2	System Overview	29
2.3	Processor Initialization	29
2.3.1	BSC Initialization	30
2.3.2	AP Initialization	30
2.3.3	Using L2 Cache as General Storage During Boot	30
2.4	Core	32
2.4.1	Compute Unit	32
2.4.2	Caches and TLBs	33
2.4.2.1	Registers Shared by Cores in a Compute Unit	33
2.4.3	Virtual Address Space	34
2.4.4	Processor Cores and Downcoring	34
2.4.4.1	Software Downcoring using D18F3x190[DisCore]	34
2.4.5	Physical Address Space	35
2.4.6	System Address Map	35
2.4.6.1	Memory Access to the Physical Address Space	35
2.4.6.1.1	Determining Memory Type	35
2.4.6.1.2	Determining The Access Destination for Core Accesses	36
2.4.7	Timers	36
2.4.8	Implicit Conditions for TLB Invalidation	36
2.4.9	Interrupts	37
2.4.9.1	Local APIC	37
2.4.9.1.1	Detecting and Enabling	37
2.4.9.1.2	APIC Register Space	37
2.4.9.1.3	ApicId Enumeration Requirements	37
2.4.9.1.4	Physical Destination Mode	38
2.4.9.1.5	Logical Destination Mode	38
2.4.9.1.6	Interrupt Delivery	38
2.4.9.1.7	Vectored Interrupt Handling	38
2.4.9.1.8	Interrupt Masking	39
2.4.9.1.9	Spurious Interrupts	39
2.4.9.1.10	Spurious Interrupts Caused by Timer Tick Interrupt	39
2.4.9.1.11	Lowest-Priority Interrupt Arbitration	39
2.4.9.1.12	Inter-Processor Interrupts	40

2.4.9.1.13	APIC Timer Operation	40
2.4.9.1.14	Generalized Local Vector Table	40
2.4.9.1.15	State at Reset	40
2.4.9.2	System Management Mode (SMM)	41
2.4.9.2.1	SMM Overview	41
2.4.9.2.2	Operating Mode and Default Register Values	41
2.4.9.2.3	SMI Sources And Delivery	42
2.4.9.2.4	SMM Initial State	42
2.4.9.2.5	SMM Save State	43
2.4.9.2.6	Exceptions and Interrupts in SMM	48
2.4.9.2.7	The Protected ASeg and TSeg Areas	48
2.4.9.2.8	SMM Special Cycles	48
2.4.9.2.9	Locking SMM	49
2.4.9.2.10	Synchronizing SMM Entry (Spring-Boarding)	49
2.4.10	Secure Virtual Machine Mode (SVM)	50
2.4.10.1	BIOS support for SVM Disable	50
2.4.11	CPUID Instruction	51
2.4.11.1	Multi-Core Support	51
2.5	Power Management	52
2.5.1	Processor Power Planes And Voltage Control	52
2.5.1.1	Serial VID Interface	52
2.5.1.1.1	SVI2 Features	52
2.5.1.2	Internal VID Registers and Encodings	53
2.5.1.2.1	MinVid and MaxVid Check	53
2.5.1.3	Low Power Features	53
2.5.1.3.1	PSIx_L Bit	53
2.5.1.3.1.1	BIOS Requirements for PSIO_L	53
2.5.1.3.2	Low Power Voltages	55
2.5.1.4	Voltage Transitions	55
2.5.1.4.1	Hardware-Initiated Voltage Transitions	55
2.5.1.4.2	Software-Initiated Voltage Transitions	55
2.5.1.4.2.1	Software-Initiated NB Voltage Transitions	55
2.5.2	Frequency and Voltage Domain Dependencies	56
2.5.2.1	Dependencies Between Cores	56
2.5.2.2	Dependencies Between Subcomponents on VDDNB	56
2.5.2.3	BIOS Requirements for Power Plane Initialization	56
2.5.3	CPU Power Management	56
2.5.3.1	Core P-states	56
2.5.3.1.1	Core P-state Naming and Numbering	57
2.5.3.1.1.1	Software P-state Numbering	57
2.5.3.1.1.2	Hardware P-state Numbering	58
2.5.3.1.2	Core P-state Control	58
2.5.3.1.3	Core P-state Visibility	59
2.5.3.1.4	Core P-state Limits	59
2.5.3.1.5	Core P-state Transition Behavior	60
2.5.3.1.6	BIOS Requirements for Core P-state Initialization and Transitions	60
2.5.3.1.7	Processor-Systemboard Power Delivery Compatibility Check	61
2.5.3.1.8	BIOS COF and VID Requirements After Warm Reset	62
2.5.3.1.8.1	Core Maximum P-state Transition Sequence After Warm Reset	63
2.5.3.1.8.2	Core Minimum P-state Transition Sequence After Warm Reset	63
2.5.3.1.8.3	ACPI Processor P-state Objects	63

2.5.3.1.8.4	Fixed ACPI Description Table (FADT) Entries	65
2.5.3.1.8.5	XPSS (Microsoft Extended PSS) Object	65
2.5.3.2	Core C-states	65
2.5.3.2.1	C-state Names and Numbers	65
2.5.3.2.2	C-state Request Interface	66
2.5.3.2.3	C-state Actions	66
2.5.3.2.3.1	C-state Probes and Cache Flushing	66
2.5.3.2.3.2	Core C1 (CC1) State	66
2.5.3.2.3.3	Core C6 (CC6) State	66
2.5.3.2.3.4	Package C6 (PC6) State	67
2.5.3.2.4	C-state Request Monitors	67
2.5.3.2.4.1	FCH Messaging	67
2.5.3.2.4.2	Cache Flush On Halt Saturation Counter	68
2.5.3.2.5	Exiting C-states	68
2.5.3.2.6	ACPI Processor C-state Objects	68
2.5.3.2.6.1	_CST	68
2.5.3.2.6.2	_CSD	69
2.5.3.2.6.3	_CRS	69
2.5.3.2.6.4	Fixed ACPI Description Table (FADT) Entries	69
2.5.3.2.7	BIOS Requirements for Initialization	69
2.5.3.3	Effective Frequency	69
2.5.4	NB Power Management	70
2.5.4.1	NB P-states	70
2.5.4.1.1	Northbridge Dynamic Power Management (NB DPM)	70
2.5.4.1.2	NB P-state Transitions	70
2.5.4.1.3	BIOS NB P-state Configuration	71
2.5.4.1.3.1	NB P-state COF and VID Synchronization After Warm Reset	71
2.5.4.1.3.2	NB P-state Transitions	72
2.5.4.1.3.3	NB P-state Configuration for Runtime	72
2.5.4.2	NB C-states	72
2.5.4.3	Fuse Power Gating	73
2.5.5	Bandwidth Requirements	73
2.5.6	GPU and Root Complex Power Management	73
2.5.6.1	Dynamic Power Management (DPM)	73
2.5.6.1.1	Activity Monitors	74
2.5.6.1.2	SCLK DPM	74
2.5.6.1.3	LCLK DPM	74
2.5.6.2	GPU and Root Complex Power Gating	74
2.5.7	DRAM Power Management	75
2.5.7.1	Memory P-states	75
2.5.7.2	DRAM Self-Refresh	75
2.5.7.3	Stutter Mode	76
2.5.7.3.1	System BIOS Requirements for Stutter Mode Operation During POST	76
2.5.7.4	EVENT_L	76
2.5.8	System Power Management	76
2.5.8.1	S-states	76
2.5.8.1.1	ACPI Suspend to RAM State (S3)	77
2.5.9	Application Power Management (APM)	77
2.5.9.1	Core Performance Boost (CPB)	77
2.5.9.1.1	C-state Boost	78
2.5.9.2	TDP Limiting	78

2.5.9.3	Bidirectional Application Power Management (BAPM)	78
2.5.9.4	Configurable TDP (cTDP)	78
2.6	Performance Monitoring	79
2.6.1	Performance Monitor Counters	79
2.6.1.1	Core Performance Monitor Counters	79
2.6.1.2	NB Performance Monitor Counters	80
2.6.2	Instruction Based Sampling (IBS)	81
2.7	Configuration Space	81
2.7.1	MMIO Configuration Coding Requirements	82
2.7.2	MMIO Configuration Ordering	82
2.7.3	Processor Configuration Space	82
2.8	Northbridge (NB)	83
2.8.1	NB Architecture	83
2.8.2	NB Routing	83
2.8.2.1	Address Space Routing	83
2.8.2.1.1	DRAM and MMIO Memory Space	83
2.8.2.1.2	IO Space	84
2.8.2.1.3	Configuration Space	84
2.8.2.1.3.1	Recommended Buffer Count Settings Overview	85
2.8.3	Memory Scrubbers	85
2.9	DRAM Controllers (DCTs)	86
2.9.1	Common DCT Definitions	86
2.9.2	DCT Frequency Support	87
2.9.3	DCT Configuration Registers	89
2.9.4	DDR Pad to Processor Pin Mapping	90
2.9.4.1	DDR Chip to Pad Mapping	91
2.9.5	DRAM Controller Direct Response Mode	92
2.9.6	DRAM Data Burst Mapping	93
2.9.7	SOC Specific Definitions	94
2.9.8	PMU	94
2.9.8.1	mboxUSPend	94
2.9.8.2	mboxUS2Pend	95
2.9.8.3	SRAM Message Block	95
2.9.9	DCT/DRAM Initialization and Resume	100
2.9.9.1	Low Voltage	101
2.9.9.2	DDR Phy Initialization	101
2.9.9.2.1	Phy General Configuration	101
2.9.9.2.2	Phy Voltage Level Programming	102
2.9.9.2.3	DRAM Channel Frequency	102
2.9.9.2.4	DRAM CAD Bus Configuration	103
2.9.9.2.5	DRAM Data Bus Configuration	108
2.9.9.2.6	Phy FIFO Configuration	114
2.9.9.2.7	Phy Predriver Initialization	115
2.9.9.2.8	Phy Auto-Calibration	118
2.9.9.2.8.1	One-Time Pre-PMU Calibration	118
2.9.9.2.8.2	Fence CalOnce	118
2.9.9.2.8.3	Auto Calibration	118
2.9.9.2.9	PMU Firmware Load	118
2.9.9.2.10	Phy Registers Required for S3 Resume	119
2.9.9.2.11	Calculating Round Trip Command Delays	119
2.9.9.3	SPD ROM-Based Configuration	119

2.9.9.3.1	DRAM ODT Pin Control	120
2.9.9.4	DCT Specific Configuration	120
2.9.9.4.1	DDR3 Turnaround Parameters	121
2.9.9.4.1.1	TrdrdBan, TrdrdSdSc, TrdrdSdDc, and TrdrdDd (Rd->Rd Timing)	121
2.9.9.4.1.2	TwrrwrSdSc, TwrrwrSdDc, TwrrwrDd (Wr->Wr Timing)	121
2.9.9.4.1.3	Twrrd (Write to Read DIMM Termination Turn-around)	122
2.9.9.4.1.4	TrwtTO (Read-to-Write Turnaround for Data, DQS Contention)	122
2.9.9.5	DRAM Device Initialization and Training	122
2.9.9.6	DRAM Training	123
2.9.9.6.1	Training MaxRdLatency	123
2.9.9.7	Synchronous Channel Initialization	123
2.9.9.8	DRAM Channel Disable	124
2.9.9.9	DRAM Phy Power Savings	124
2.9.10	Continuous Pattern Generation	126
2.9.10.1	DCT Training Pattern Generation	126
2.9.10.1.1	Activate and Precharge Command Generation	126
2.9.10.1.2	Read and Write Command Generation	127
2.9.10.1.3	Data Comparison	128
2.9.10.1.4	BubbleCnt and CmdStreamLen Programming	128
2.9.11	Memory Interleaving Modes	129
2.9.11.1	Chip Select Interleaving	130
2.9.11.2	Channel Interleaving	132
2.9.11.2.1	Four Channel Interleaving	132
2.9.12	Memory Hoisting	132
2.9.12.1	DramHoleOffset Programming	132
2.9.12.2	DctSelBaseOffset Programming	134
2.9.13	DRAM CC6/PC6 Storage	136
2.9.13.1	Fixed Storage	136
2.9.14	DRAM On DIMM Thermal Management and Power Capping	137
2.10	Thermal Functions	139
2.10.1	The Tctl Temperature Scale	139
2.10.2	Temperature Slew Rate Control	140
2.10.3	Temperature-Driven Logic	140
2.10.3.1	PROCHOT_L and Hardware Thermal Control (HTC)	140
2.10.3.2	Software P-state Limit Control	141
2.10.3.3	THERMTRIP	141
2.11	Root Complex	142
2.11.1	Overview	142
2.11.2	Interrupt Routing	143
2.11.2.1	IOAPIC Configuration	143
2.11.3	Links	144
2.11.3.1	Overview	144
2.11.3.2	Link Configurations	144
2.11.4	Root Complex Configuration	146
2.11.4.1	LPC MMIO Requirements	146
2.11.4.2	Configuration for non-FCH Bridges	146
2.11.4.3	Link Configuration and Initialization	146
2.11.4.3.1	Link Configuration and Core Initialization	147
2.11.4.3.2	Link Training	147
2.11.4.4	Miscellaneous Features	147
2.11.4.4.1	Lane Reversal	147

2.11.4.4.2	Link Speed Changes	148
2.11.4.4.2.1	Autonomous Link Speed Changes	148
2.11.4.4.3	Deemphasis	148
2.11.4.5	Link Power Management	148
2.11.4.5.1	Link States	148
2.11.4.5.2	Dynamic Link-width Control	148
2.11.4.6	Link Test and Debug Features	149
2.11.4.6.1	Compliance Mode	149
2.11.5	FCH Messages	149
2.11.6	BIOS Timer	149
2.11.7	PCIe Client Interface Control	149
2.12	IOMMU	151
2.12.1	IOMMU Configuration Space	151
2.12.2	IOMMU Initialization	151
2.12.2.1	IOMMU L1 Initialization	151
2.12.2.2	IOMMU L2 Initialization	152
2.12.2.3	IOMMU SMI Filtering	152
2.13	System Management Unit (SMU)	153
2.13.1	Software Interrupts	153
2.14	Graphics Processor (GPU)	153
2.14.1	Graphics Memory Controller (GMC)	153
2.14.2	Frame Buffer (FB)	154
2.15	RAS Features	155
2.15.1	Machine Check Architecture	155
2.15.1.1	Machine Check Registers	155
2.15.1.2	Machine Check Errors	156
2.15.1.3	Error Detection, Action, Logging, and Reporting	157
2.15.1.3.1	MCA conditions that cause Shutdown	158
2.15.1.3.2	Error Logging During Overflow	158
2.15.1.4	MCA Initialization	159
2.15.1.5	Error Code	160
2.15.1.6	Handling Machine Check Exceptions	161
2.15.1.6.1	Differentiation Between System-Fatal and Process-Fatal Errors	163
2.15.1.7	Error Thresholding	164
2.15.1.8	Scrub Rate Considerations	165
2.15.1.9	Error Diagnosis	166
2.15.1.9.1	Common Diagnosis Information	167
2.15.1.10	Deferred Errors and Data Poisoning	168
2.15.2	DRAM ECC Considerations	169
2.15.2.1	ECC Syndromes	169
2.15.2.1.1	x4 ECC	169
2.15.3	Error Injection and Simulation	171
2.15.3.1	DRAM Error Injection	171
2.15.4	GIO RAS	172
<b>3</b>	<b>Registers</b>	<b>173</b>
3.1	Register Descriptions and Mnemonics	173
3.1.1	Northbridge MSRs In Multi-Core Products	175
3.1.2	Software Recommendation (BIOS, SBIOS)	175
3.1.3	See Keyword (See:)	176
3.1.4	Mapping Tables	176

3.1.4.1	Register Mapping	176
3.1.4.2	Index Mapping	176
3.1.4.3	Field Mapping	176
3.1.4.4	Broadcast Mapping	176
3.1.4.5	Reset Mapping	177

# Revision History

KV BKDG Revision 3.01 Changes, Feb 19, 2014, PUB release

- [2.12.2.3 \[IOMMU SMI Filtering\]](#): Updated.
- [2.14.2 \[Frame Buffer \(FB\)\]](#): Updated.
- [2.15.1.3.2 \[Error Logging During Overflow\]](#): Table 48 Updated.
- [APIC300\[DS\]](#): Updated.
- [D0F0xBC\[NbSmuIndData\]](#): Updated.
- [D0F0xD4\[NbGbifIndData\]](#): Updated.
- [D0F2x70\[NxSupW\]](#): Updated.
- [D18F0x\[F0,D0,B0,90\] \[Link Base Channel Buffer Count\]](#): Updated.
- [D18F3x160 \[NB Machine Check Misc \(DRAM Thresholding\) 0 \(MC4\\_MISC0\)\]](#): Updated.

KV BKDG Revision 3.00 Changes, Jan 10, 2014, Initial Public release

## 1 Overview

This document defines AMD Family 15h Models 30h-3Fh Processors, henceforth referred to as the processor.

- The processor overview is located at [2.1 \[Processor Overview\]](#).
- The processor is distinguished by the combined ExtFamily and BaseFamily fields of the CPUID instruction (see [CPUID Fn8000\\_0001\\_EAX](#) in [3.18 \[CPUID Instruction Registers\]](#)).

### 1.1 Intended Audience

This document provides the processor behavioral definition and associated design notes. It is intended for platform designers and for programmers involved in the development of low-level BIOS (basic input/output system) functions, drivers, and operating system kernel modules. It assumes prior experience in personal computer platform design, microprocessor programming, and legacy x86 and AMD64 microprocessor architecture. The reader should also have familiarity with various platform technologies, such as DDR DRAM.

### 1.2 Reference Documents

- Advanced Configuration and Power Interface (ACPI) Specification. [www.acpi.info](http://www.acpi.info).
- AMD64 Architecture Programmer's Manual Volume 1: Application Programming, #24592.
- AMD64 Architecture Programmer's Manual Volume 2: System Programming, #24593.
- AMD64 Architecture Programmer's Manual Volume 3: Instruction-Set Reference, #24594.
- AMD64 Architecture Programmer's Manual Volume 4: 128-Bit and 256-Bit Media Instructions, #26568.
- AMD64 Architecture Programmer's Manual Volume 5: 64-Bit Media and x87 Floating-Point Instructions, #26569.
- AMD I/O Virtualization Technology (IOMMU) Specification, #34434.
- Software Optimization Guide for AMD Family 15h Processors, #47414.
- Revision Guide for AMD Family 15h Models 30h-3Fh Processors, #51603.
- JEDEC standards. [www.jedec.org](http://www.jedec.org).
- PCI local bus specification. ([www.pcisig.org](http://www.pcisig.org)).
- PCI Express® specification. ([www.pcisig.org](http://www.pcisig.org)).
- AMD64 Technology Lightweight Profiling Specification, #43724.

### 1.3 Conventions

#### 1.3.1 Numbering

- **Binary numbers.** Binary numbers are indicated by appending a “b” at the end, e.g., 0110b.
- **Decimal numbers.** Unless specified otherwise, all numbers are decimal. This rule does not apply to the register mnemonics described in [3.1 \[Register Descriptions and Mnemonics\]](#); register mnemonics all utilize hexadecimal numbering.
- **Hexadecimal numbers.** hexadecimal numbers are indicated by appending an “h” to the end, e.g., 45f8h.
- **Underscores in numbers.** Underscores are used to break up numbers to make them more readable. They do not imply any operation. E.g., 0110\_1100b.

### 1.3.2 Arithmetic And Logical Operators

In this document, formulas generally follow Verilog conventions for logic equations.

**Table 1: Arithmetic and Logical Operators**

Operator	Definition
{}	Concatenation. Curly brackets are used to indicate a group of bits that are concatenated together. Each set of bits is separated by a comma. E.g., {Addr[3:2], Xlate[3:0]} represents a 6-bit value; the two MSBs are Addr[3:2] and the four LSB's are Xlate[3:0].
	Bitwise OR. E.g. (01b   10b == 11b).
	Logical OR. E.g. (01b    10b == 1b); treats multibit operand as 1 if >=1 and produces a 1-bit result.
&	Bitwise AND. E.g. (01b & 10b == 00b).
&&	Logical AND. E.g. (01b && 10b == 1b); logical treats multibit operand as 1 if >=1 and produces a 1-bit result.
^	Bitwise exclusive-OR. E.g. (01b ^ 10b == 11b). Sometimes used as “raised to the power of” as well, as indicated by the context in which it is used. E.g. (2^2 == 4).
~	Bitwise NOT. (also known as one's complement). E.g. (~10b == 01b).
!	Logical NOT. E.g. (!10b == 0b); treats multibit operand as 1 if >=1 and produces a 1-bit result.
<, <=, >, >=, ==, !=	Relational. Less than, Less than or equal, greater, greater than or equal, equal, and not equal.
+, -, *, /, %	Arithmetic. Addition, subtraction, multiplication, division, and modulus.
<<	Bitwise left shift. Shift left first operand by the number of bits specified by the 2nd operand. E.g. (01b << 01b == 10b).
>>	Bitwise right shift. Shift right first operand by the number of bits specified by the 2nd operand. E.g. (10b >> 01b == 01b).
?:	Ternary conditional. E.g. <i>condition ? value if true : value if false</i> . Equivalent to IF <i>condition</i> THEN <i>value if true</i> ELSE <i>value if false</i> .

**Table 2: Functions**

Function	Definition
ABS	ABS(integer-expression): Remove sign from signed value.
FLOOR	FLOOR(integer-expression): Rounds real number down to nearest integer.
CEIL	CEIL(real-expression): Rounds real number up to nearest integer.
MIN	MIN(integer-expression-list): Picks minimum integer or real value of comma separated list.
MAX	MAX(integer-expression-list): Picks maximum integer or real value of comma separated list.
COUNT	COUNT(integer-expression): Returns the number of binary 1's in the integer.

**Table 2: Functions**

Function	Definition
ROUND	ROUND(real-expression): Rounds to the nearest integer; halfway rounds away from zero.
UNIT	UNIT(fieldName UnitOfMeasure): Input operand is a register field name that defines all values with the same unit of measure. Returns the value expressed in the unit of measure for the current value of the register field.
POW	POW(base, exponent): POW(x,y) returns the value x to the power of y.

### 1.3.3 Operator Precedence and Associativity

This document follows C operator precedence and associativity. The following table lists operator precedence (highest to lowest). Their associativity indicates in what order operators of equal precedence in an expression are applied. Parentheses are also used to group sub-expressions to force a different precedence; such parenthetical expressions can be nested and are evaluated from inner to outer. E.g. “X = A | ~B & C” is the same as “X = A | ((~B) & C)”.

**Table 3: Operator Precedence and Associativity**

Operator	Description	Associativity
!, ~	Logical negation/bitwise complement	right-to-left
*, /, %	Multiplication/division/modulus	left-to-right
+, -	Addition/subtraction	left-to-right
<<, >>	Bitwise shift left, Bitwise shift right	left-to-right
<, <=, >, >=, ==, !=	Relational operators	left-to-right
&	Bitwise AND	left-to-right
^	Bitwise exclusive OR	left-to-right
	Bitwise inclusive OR	left-to-right
&&	Logical AND	left-to-right
	Logical OR	left-to-right
?:	Ternary conditional	right-to-left

## 1.4 Definitions

**Table 4: Definitions**

Term	Definition
AP	Application processor. See <a href="#">2.3 [Processor Initialization]</a> .
BAPM	Bidirectional Application Power Management. See <a href="#">2.5.9.3 [Bidirectional Application Power Management (BAPM)]</a> .
Battery-Power	The system is running from a battery power source or otherwise undocked from a continuous power supply. Setting using this definition may be required to change during runtime.
BCS	Base configuration space. See <a href="#">2.7 [Configuration Space]</a> .

**Table 4: Definitions**

Term	Definition
<b>BERT</b>	Bit error rate tester. A piece of test equipment that generates arbitrary test patterns and checks that a device under test returns them without errors.
<b>BIST</b>	Built-in self-test. Hardware within the processor that generates test patterns and verifies that they are stored correctly (in the case of memories) or received without error (in the case of links).
<b>Boot VID</b>	Boot voltage ID. This is the VDD and VDDNB voltage level that the processor requests from the external voltage regulator during the initial phase of the cold boot sequence. See <a href="#">2.5.1.2 [Internal VID Registers and Encodings]</a> .
<b>BCD</b>	Binary coded decimal number format.
<b>BSC</b>	Boot strap core. Core 0 of the <a href="#">BSP</a> . Specified by <a href="#">MSR0000_001B[BSC]</a> .
<b>BSP</b>	Boot strap processor. See <a href="#">2.3 [Processor Initialization]</a> .
<b>CAR</b>	Use of the L2 cache as RAM during boot. See <a href="#">2.3.3 [Using L2 Cache as General Storage During Boot]</a> .
<b>C-states</b>	These are ACPI-defined core power states. C0 is operational. All other C-states are low-power states in which the processor is not executing code. See <a href="#">2.5.3.2 [Core C-states]</a> .
<b>Canonical address</b>	An address in which the state of the most-significant implemented bit is duplicated in all the remaining higher-order bits, up to bit 63.
<b>Channel</b>	See DRAM channel.
<b>Channel interleaved mode</b>	Mode in which DRAM address space is interleaved between DRAM channels. See <a href="#">2.9.11 [Memory Interleaving Modes]</a> .
<b>CMP</b>	Chip multi-processing. Refers to processors that include multiple cores. See <a href="#">2.1 [Processor Overview]</a> .
<b>COF</b>	Current operating frequency of a given clock domain. See <a href="#">2.5.3 [CPU Power Management]</a> .
<b>Cold reset</b>	PWROK is deasserted and RESET_L is asserted. See <a href="#">2.3 [Processor Initialization]</a> .
<b>Compute Unit</b>	Two <a href="#">Cores</a> that share IC, DE, FP and L2 resources. See <a href="#">2.1 [Processor Overview]</a> .
<b>Core</b>	The instruction execution unit of the processor. See <a href="#">2.1 [Processor Overview]</a> .
<b>CPB</b>	Core performance boost. See <a href="#">2.5.9.1 [Core Performance Boost (CPB)]</a> .
<b>CpuCore-Num</b>	Specifies the core number. See <a href="#">2.4.4 [Processor Cores and Downcoring]</a> .
<b>CPUID function X</b>	Refers to the CPUID instruction when EAX is preloaded with X. See <a href="#">3.18 [CPUID Instruction Registers]</a> .
<b>CS</b>	Chip select. See <a href="#">D18F2x[5C:40]_dct[3:0] [DRAM CS Base Address]</a> .
<b>DCT</b>	DRAM controller. See <a href="#">2.9 [DRAM Controllers (DCTs)]</a> .
<b>DCQ</b>	DRAM controller queue.
<b>DDR3</b>	DDR3 memory technology. See <a href="#">2.9 [DRAM Controllers (DCTs)]</a> .
<b>DID</b>	Divisor identifier. Specifies the post-PLL divisor used to reduce the COF. See <a href="#">2.5.3 [CPU Power Management]</a> .
<b>Doubleword</b>	A 32-bit value.
<b>Downcoring</b>	Removal of cores. See <a href="#">2.4.4 [Processor Cores and Downcoring]</a> .

Table 4: Definitions

Term	Definition
<b>DRAM channel</b>	The part of the DRAM interface that connects to a DIMM. See <a href="#">2.9 [DRAM Controllers (DCTs)]</a> .
<b>Dual-Plane</b>	Refers to a processor or systemboard where VDD and VDDNB are separate and may operate at independent voltage levels. Refer to <a href="#">2.5.1 [Processor Power Planes And Voltage Control]</a> .
<b>DW</b>	Doubleword. A 32-bit value.
<b>ECS</b>	Extended configuration space. See <a href="#">2.7 [Configuration Space]</a> .
<b>EDS</b>	Electrical data sheet. See <a href="#">1.2 [Reference Documents]</a> .
<b>FCH</b>	Fusion Controller Hub. The platform device that contains the bridge to the system BIOS.
<b>FDS</b>	Functional data sheet; there is one FDS for each package type.
<b>FID</b>	Frequency identifier. Specifies the PLL frequency multiplier for a given clock domain. See <a href="#">2.5.3 [CPU Power Management]</a> .
<b>FreeR-unSample-Timer</b>	An internal free running timer used by many power management features. The timer increments at the rate specified by <a href="#">D18F4x110[CSampleTimer]</a> .
<b>GB</b>	Gbyte or Gigabyte; 1,073,741,824 bytes.
<b>#GP</b>	A general-protection exception.
<b>#GP(0)</b>	Notation indicating a general-protection exception (#GP) with error code of 0.
<b>GpuEnabled</b>	GpuEnabled = ( <a href="#">D1F0x00!</a> =FFFF_FFFFh).
<b>GT/s</b>	Giga-transfers per second.
<b>HCD</b>	Host Controller Driver. A software component.
<b>HTC</b>	Hardware thermal control. See <a href="#">2.10.3.1 [PROCHOT_L and Hardware Thermal Control (HTC)]</a> .
<b>HTC-active state</b>	Hardware-controlled lower-power, lower-performance state used to reduce temperature. See <a href="#">2.10.3.1 [PROCHOT_L and Hardware Thermal Control (HTC)]</a> .
<b>IBS</b>	Instruction based sampling. See <a href="#">2.6.2 [Instruction Based Sampling (IBS)]</a> .
<b>IFCM</b>	Isochronous flow-control mode, as defined in the link specification.
<b>ILM</b>	Internal loopback mode. Mode in which the link receive lanes are connected directly to the transmit lanes of the same link for testing and characterization. See <a href="#">D18F0x[18C:170] [Link Extended Control]</a> .
<b>IO configuration</b>	Access to configuration space through IO ports CF8h and CFCh. See <a href="#">2.7 [Configuration Space]</a> .
<b>IORR</b>	IO range register. See <a href="#">MSRC001_00[18,16] [IO Range Base (IORR_BASE[1:0])]</a> .
<b>IOMMU</b>	I/O Memory Management Unit. Also known as AMD Virtualization™ Technology.
<b>KB</b>	Kbyte or Kilobyte; 1024 bytes.
<b>L1 cache</b>	The level 1 caches (instruction cache and the data cache) and the level 2 caches. See <a href="#">2.1 [Processor Overview]</a> .
<b>L2 cache</b>	
<b>Linear (virtual) address</b>	The address generated by a core after the segment is applied.
<b>Link</b>	Generic term that refers to a refer to PCIe® link.
<b>LINT</b>	Local interrupt.

Table 4: Definitions

Term	Definition
<b>Logical address</b>	The address generated by a core before the segment is applied.
<b>LVT</b>	Local vector table. A collection of APIC registers that define interrupts for local events. E.g., <a href="#">APIC[530:500] [Extended Interrupt [3:0] Local Vector Table]</a> .
<b>Master abort</b>	This is a PCI-defined term that is applied to transactions on other than PCI buses. It indicates that the transaction is terminated without affecting the intended target; reads return all 1's; writes are discarded; the master abort error code is returned in the response, if applicable; master abort error bits are set if applicable.
<b>MB</b>	Megabyte; 1024 KB.
<b>MCT</b>	Memory controller. See <a href="#">2.8 [Northbridge (NB)]</a> .
<b>MCQ</b>	Memory controller queue. See <a href="#">2.8 [Northbridge (NB)]</a> .
<b>Micro-op</b>	Micro-op. Instructions have variable-length encoding and many perform multiple primitive operations. The processor does not execute these complex instructions directly, but, instead, decodes them internally into simpler fixed-length instructions called macro-ops. Processor schedulers subsequently break down macro-ops into sequences of even simpler instructions called micro-ops, each of which specifies a single primitive operation. See <i>Software Optimization Guide for AMD Family 15h Processors</i> .
<b>MEMCLK</b>	Refers to the clock signals, M[B, A][3:0]_CLK, that are driven from the processor to DDR DIMMs.
<b>MMIO</b>	Memory-mapped input-output range. This is physical address space that is mapped to the IO functions such as the IO links or MMIO configuration. The IO link MMIO ranges are specified by <a href="#">D18F1x[2CC:2A0,1CC:180,BC:80] [MMIO Base/Limit]</a> .
<b>MMIO configuration</b>	Access to configuration space through memory space. See <a href="#">2.7 [Configuration Space]</a> .
<b>MSR</b>	Model-specific register. The core includes several MSRs for general configuration and control. See <a href="#">3.19 [MSRs - MSR0000_xxxx]</a> for the beginning of the MSR register definitions.
<b>MTRR</b>	Memory-type range register. The MTRRs specify the type of memory associated with various memory ranges. See <a href="#">MSR0000_00FE</a> , <a href="#">MSR0000_020[F:0]</a> , <a href="#">MSR0000_02[6F:68,59:58,50]</a> , and <a href="#">MSR0000_02FF</a> .
<b>NB</b>	Northbridge. The transaction routing block of the node. See <a href="#">2.1 [Processor Overview]</a> .
<b>NBC</b>	NBC = ( <a href="#">CPUID Fn0000_0001_EBX[LocalApicId[3:0]]==0</a> ). Node Base Core. The lowest numbered core in the node.
<b>NBPMC</b>	Performance monitor counter. See <a href="#">2.6.1.2 [NB Performance Monitor Counters]</a> .
<b>NCLK</b>	The main northbridge clock. The NCLK frequency is the NB COF.
<b>Node</b>	See <a href="#">2.1 [Processor Overview]</a> .
<b>Normalized address</b>	Addresses used by DCTs. See <a href="#">2.8 [Northbridge (NB)]</a> .
<b>OW</b>	Octword. An 128-bit value.
<b>ODM</b>	On-DIMM mirroring. See <a href="#">D18F2x[5C:40]_dct[3:0][OnDimmMirror]</a> .
<b>ODT</b>	On-die termination, which is applied DRAM interface signals.
<b>ODTS</b>	DRAM On-die thermal sensor.
<b>Operational frequency</b>	The frequency at which the processor operates. See <a href="#">2.5 [Power Management]</a> .

**Table 4: Definitions**

Term	Definition
<b>PCIe®</b>	PCI Express®.
<b>PDS</b>	Product data sheet.
<b>Physical address</b>	Addresses used by cores in transactions sent to the NB.
<b>PMC</b>	Performance monitor counter. See <a href="#">2.6.1.1 [Core Performance Monitor Counters]</a> .
<b>PRBS</b>	Pseudo-random bit sequence.
<b>Processor</b>	See <a href="#">2.1 [Processor Overview]</a> .
<b>PSI</b>	Power Status Indicator. See <a href="#">2.5.1.3.1 [PSIx_L Bit]</a> .
<b>P-state</b>	Performance state. See <a href="#">2.5 [Power Management]</a> .
<b>PTE</b>	Page table entry.
<b>QW</b>	Quadword. A 64-bit value.
<b>RAS</b>	Reliability, availability and serviceability (industry term). See <a href="#">2.15.1 [Machine Check Architecture]</a> .
<b>RDQ</b>	Read data queue.
<b>REFCLK</b>	Reference Clock, refers to the clock frequency (100 MHz) or the clock period (10 ns) depending on the context used.
<b>RX</b>	Receiver.
<b>Scrubber</b>	Background memory checking logic. See <a href="#">2.8.3 [Memory Scrubbers]</a> .
<b>Shutdown</b>	A state in which the affected core waits for either INIT, RESET, or NMI. When shutdown state is entered, a shutdown special cycle is sent on the IO links.
<b>Single-Plane</b>	Refers to a processor or systemboard where VDD and VDDNB are tied together and operate at the same voltage level. Refer to <a href="#">2.5.1 [Processor Power Planes And Voltage Control]</a> .
<b>Slam</b>	Refers to changing the voltage to a new value in one step (as opposed to stepping). See <a href="#">2.5.1.4.1 [Hardware-Initiated Voltage Transitions]</a> .
<b>SMAF</b>	System management action field. This is the code passed from the SMC to the processors in STPCLK assertion messages. The action taken by the processors in response to this message is specified by <a href="#">D18F3x[84:80] [ACPI Power State Control]</a> .
<b>SMBus</b>	System management bus. Refers to the protocol on which the serial VID interface (SVI) commands are based. See <a href="#">2.5.1 [Processor Power Planes And Voltage Control]</a> , and <a href="#">1.2 [Reference Documents]</a> .
<b>SMC</b>	System management controller. This is the platform device that communicates system management state information to the processor through an IO link, typically the system IO hub.
<b>SMI</b>	System management interrupt. See <a href="#">2.4.9.2.1 [SMM Overview]</a> .
<b>SMM</b>	System management mode. See <a href="#">2.4.9.2 [System Management Mode (SMM)]</a> .
<b>Speculative event</b>	A performance monitor event counter that counts all occurrences of the event even if the event occurs during speculative code execution.
<b>SVI2</b>	Serial VID 2.0 interface. See <a href="#">2.5.1.1 [Serial VID Interface]</a> .
<b>SVM</b>	Secure virtual machine. See <a href="#">2.4.10 [Secure Virtual Machine Mode (SVM)]</a> .
<b>Sync flood</b>	The propagation of continuous sync packets to all links. This is used to quickly stop the transmission of potentially bad data when there are no other means to do so. See the link specification for additional information.

**Table 4: Definitions**

Term	Definition
<b>TCC</b>	Temperature calculation circuit. See <a href="#">2.10 [Thermal Functions]</a> .
<b>Tctl</b>	Processor temperature control value. See <a href="#">2.10.3 [Temperature-Driven Logic]</a> .
<b>TDC</b>	Thermal design current. See the AMD Infrastructure Roadmap, #41482.
<b>TDP</b>	Thermal design power. A power consumption parameter that is used in conjunction with thermal specifications to design appropriate cooling solutions for the processor. See <a href="#">2.5.9.2 [TDP Limiting]</a> .
<b>Token</b>	A scheduler entry used in various northbridge queues to track outstanding requests. See <a href="#">D18F3x140 [SRI to XCS Token Count]</a> on Page 461.
<b>TX</b>	Transmitter.
<b>UI</b>	Unit interval. This is the amount of time equal to one half of a clock cycle.
<b>UMI</b>	Unified Media Interface. The link between the processor and the FCH.
<b>VDD</b>	Main power supply to the processor core logic.
<b>VDDNB</b>	Main power supply to the processor NB logic.
<b>VID</b>	Voltage level identifier. See <a href="#">2.5.1 [Processor Power Planes And Voltage Control]</a> .
<b>Virtual CAS</b>	The clock in which CAS is asserted for the burst, N, plus the burst length (in MEMCLKs), minus 1; so the last clock of virtual CAS = $N + (BL/2) - 1$ .
<b>VRM</b>	Voltage regulator module.
<b>W</b>	Word. A 16-bit value.
<b>Warm reset</b>	RESET_L is asserted only (while PWROK stays high). See <a href="#">2.3 [Processor Initialization]</a> .
<b>WDT</b>	Watchdog timer. A timer that detects activity and triggers an error if a specified period of time expires without the activity. For example, see <a href="#">MSRC001_0074 [CPU Watchdog Timer (Cpu-WdtCfg)]</a> or the NB watchdog timer in <a href="#">D18F3x40 [MCA NB Control]</a> .
<b>WDQ</b>	Write data queue.
<b>XBAR</b>	Cross bar; command packet switch. See <a href="#">2.8 [Northbridge (NB)]</a> .

## 1.5 Changes Between Revisions and Product Variations

### 1.5.1 Revision Conventions

The processor revision is specified by [CPUID Fn0000\\_0001\\_EAX \[Family, Model, Stepping Identifiers\]](#) or [CPUID Fn8000\\_0001\\_EAX \[Family, Model, Stepping Identifiers\]](#). This document uses a revision letter instead of specific model numbers. The following table contains the definitions based on model and stepping used in this document. Where applicable, the processor stepping is indicated after the revision letter. All behavior marked with a revision letter apply to future revisions unless they are superseded by a change in a later revision. See the revision guide for additional information about revision determination. See [1.2 \[Reference Documents\]](#).

**Table 5: Processor revision conventions**

Term	Definition
<b>PROC</b>	Processor. PROC = {CPUID Fn0000_0001_EAX[ExtFamily], {CPUID Fn0000_0001_EAX[ExtModel], CPUID Fn0000_0001_EAX[BaseModel]}, CPUID Fn0000_0001_EAX[Stepping]}.
<b>KV_A1</b>	KV_A1 = {06h,30h,1h}.

### 1.5.2 Major Changes

This section describes the major changes relative to Family 15h Models 10h-1Fh Processors.

- CPU core changes:
  - Architectural changes:
    - XSAVEOPT: Added XSAVE optimization. Reported by CPUID Fn0000\_000D\_EAX\_x1[XSAVE-OPT].
    - PTSC: Added “Performance Time Stamp Counter” that is a synchronized value across all cores and the GPU. Used by LWP. See MSRC001\_0280. Reported by CPUID Fn8000\_0001\_ECX[PerfTsc] and CPUID Fn8000\_0008\_ECX[PerfTscSize].
    - DataBreakpointExtension: Added debug breakpoint address matching enhancement. See CPUID Fn8000\_0001\_ECX[DataBreakpointExtension], MSRC001\_1027[31:12], and MSRC001\_101[B:9].
    - LWP: Added LWP support for Global Timestamp Counter and Continuous Wrapping Mode. See CPUID Fn8000\_001C\_EAX[LwpPTSC, LwpCont], MSRC000\_0105[LwpPTSC, LwpCont], CPUID Fn8000\_001C\_EDX[LwpPTSC, LwpCont].
    - PCID: Added software ASID support. Reported by CPUID Fn0000\_0001\_ECX[PCID].
    - FSGSBASE: Add ability for user code to write FS and GS segments. This facilitates user mode scheduling of threads. Reported by CPUID Fn0000\_0007\_EBX\_x0[FSGSBASE].
  - IPC changes:
    - Store to load forwarding optimization.
    - Dispatch and retire up to 2 stores per cycle.
    - Improved memfile, from last 3 stores to last 8 stores, and allow tracking of dependent stack operations.
    - Load queue (LDQ) size increased to 48, from 44.
    - Store queue (STQ) size increased to 32, from 24.
    - Increase dispatch bandwidth to 8 INT ops per cycle (4 to each core), from 4 INT ops per cycle (4 to just 1 core). 4 ops per cycle per core remains unchanged.
    - Accelerate SYSCALL/SYSRET.
    - Increased L2 BTB size from 5K to 10K and from 8 to 16 banks.
    - Added L2 BTB extended target array. Provides full physical address when relative address is insufficient.
    - Improved branch prediction.
    - Improved loop prediction.
    - Increase PFB from 8 to 16 entries; the 8 additional entries can be used either for prefetch or as a loop buffer.
    - Increase snoop tag throughput.
    - Change from 4 to 3 FP pipe stages.
  - MSR Changes:
- Cache changes:
  - IC: Increased from 64 KB (2-way) to 96 KB (3-way).
- TLB changes:
- Memory controller changes:

- Links and IO changes:
- RAS-related changes:
  - L2 single bit errors corrected in array; L2 single bit errors corrected previously only corrected/poisoned to requestor, leaving single bit error in array.
- Northbridge changes:
- Power management changes:
  - Dynamic L2 Power Gating. Reduce L2 leakage by reducing the number of L2 ways on C6 exit according to usage.
- Core/NB performance counter changes:
  - Increase Onion Bandwidth. Double to 32Byte width in each direction.
  - Add coherency for FSA. Add FSA 0.85 support.
    - Add second onion bus
    - Support for PCIe® and OpenCL™ atomics:
    - Config bit to enable command throttling on onion
  - Add support for GNB DSM
    - Incorporate StopClocks from GNB:
    - Incorporate Cross Triggers from GNB:
    - Incorporate SelfRefresh, HTReceiveDisable from GNB
  - Bandwidth Improvements
    - Local probe responses bypass SRQ -> MCT
    - Send SrcDone based on TgtDone
    - Two commands per clock from MCT/XBR -> SRQ
    - Two commands per clock from SRI -> MCQ; MCQ can sink two responses/clock
    - SRQ/SRA/SRD +16 (see SRQ Changes)
    - MCQ +16
    - LCS/LPS +16
    - Improve write holding register bandwidth
  - Supply DRAM utilization as a frequency sensitivity hint to the OS
  - Memory parking performance counters. Over time shift traffic from all channels to one channel.
  - Add onion bus.
  - Add PCIe® endpoint mode.
  - 2 or 3 core-pairs Add 3 CU support.
  - Buffer size changes
  - SMU Pstate Control

### 1.5.2.1 Major Changes to Core/NB Performance Counters

Major Changes to Core/NB Performance Counters:

- Core performance counters:
  - [PMCx000\[7,3\]](#): Changed to reserved; Removed pipe 3.
  - [PMCx042 \[Data Cache Refills from L2 or System\]](#): Added [4].
  - [PMCx060](#), [PMCx061\[5:0\]](#), [PMCx062](#), [PMCx063](#), [PMCx064](#): Added.
  - [PMCx186 \[Uops Dispatched From Decoder\]](#): Added.
  - [PMCx0D1](#), [PMCx0D5-PMCx0D8](#), [PMCx1D8](#), [PMCx1DD-PMCx1DE](#): These events count even when dispatch selects the other core of the compute-unit.
  - [PMCx1D0 \[Retired Fused Branch Instructions\]](#): Added.
  - [PMCx1DF \[FP Dispatch Contention\]](#): Changed.

## 2 Functional Description

### 2.1 Processor Overview

The *processor* is defined as follows:

- The processor is a package that contains one node.
- Supports x86-based instruction sets.
- Packages:
  - FM2r2: Desktop Package.
  - FP3: Notebook Package.
  - See [CPUID Fn8000\\_0001\\_EBX\[PkgType\]](#).
- Compute Unit
  - 2 cores per compute unit. Up to 2 compute units.
  - 2 MB L2
  - See [2.4.1 \[Compute Unit\]](#).
- DRAM:
  - Configurable to two 64-bit DDR3 memory channels (A, B). See [Figure 2 \[A processor\]](#).
  - ECC: Yes.
  - Max speed: 2133 MT/s (1.5V).
  - See [2.9.2](#) for voltage control affecting DRAM speed.
- Northbridge:
  - One communication packet routing block referred to as the northbridge (NB). The NB routes transactions between the cores, the link, and the DRAM interfaces. It includes the configuration register space for the device.
- Graphics northbridge:
  - Links:
    - PCIe® Gen3 on Gfx link, PCIe® Gen2 on the GPP links and PCIe® Gen2 on the UMI link.
    - Gfx lanes: One x16, GPP lanes: One x4, UMI lanes: One x4.
    - See [2.11.3 \[Links\]](#).
    - See [2.11.3.1](#) for voltage control affecting data rate of the Gfx link .
- Power Management:
  - See [2.5 \[Power Management\]](#).
- RAS:
  - See [2.15 \[RAS Features\]](#).

Figure 1: A Compute Unit

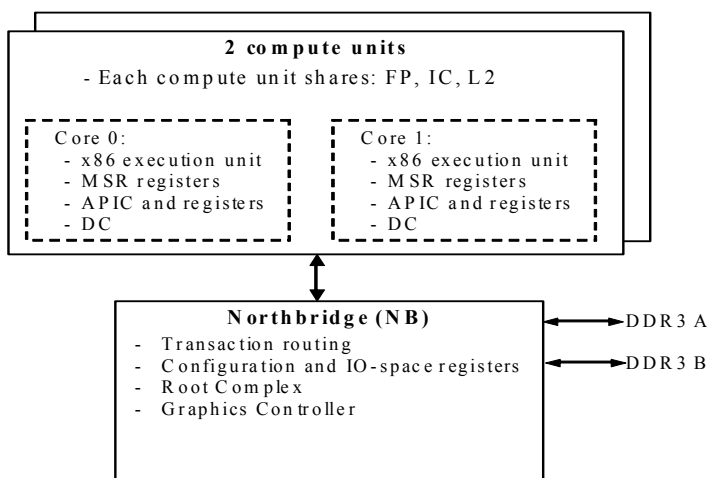

Figure 2: A processor

## 2.2 System Overview

## 2.3 Processor Initialization

This section describes the initialization sequence after a cold reset.

Core 0 of the processor, the bootstrap core (BSC), begins executing code from the reset vector. The remaining cores do not fetch code until their enable bits are set ([D18F0x1DC\[CpuEn\]](#)).

### 2.3.1 BSC Initialization

The BSC must perform the following tasks as part of boot.

- Store BIST information from the EAX register into an unused processor register.
- [D18F0x6C](#)[InitDet] may be used by BIOS to differentiate between INIT and cold/warm reset.
- Determine type of startup using [D18F0x6C](#)[ColdRstDet].
  - If this is a warm reset then BIOS may check for valid MCA errors and if present save the status for later use. See [2.15.1.6 \[Handling Machine Check Exceptions\]](#).
- Enable the cache, program the MTRRs for [CAR](#) and initialize [CAR](#). See [2.3.3 \[Using L2 Cache as General Storage During Boot\]](#).
- Setup the SMU.
- Setup of APIC ([2.4.9.1.3 \[ApicId Enumeration Requirements\]](#)).
- Setup the link configuration [2.11.3.2 \[Link Configurations\]](#).
- Setup the root complex and initialize the I/O links [2.11.4.3 \[Link Configuration and Initialization\]](#).
- If required, reallocate data and flow control buffers of the links (see [D18F0x\[F0,D0,B0,90\]](#) [[Link Base Channel Buffer Count](#)] and [D18F0x\[F4,D4,B4,94\]](#) [[Link Isochronous Channel Buffer Count](#)]).
- Issue system warm reset.
- Configure the DRAM controllers.
- Configure processor power management. See [2.5 \[Power Management\]](#).
- Allow other cores to begin fetching instructions by setting [D18F0x1DC](#)[CpuEn] in the PCI configuration space of all nodes. See [2.4.4 \[Processor Cores and Downcoring\]](#).

### 2.3.2 AP Initialization

All other processor cores other than core 0 begin executing code from the reset vector. They must perform the following tasks as part of boot.

- Store BIST information from the eax register into an unused processor register.
- [D18F0x6C](#)[InitDet] may be used by BIOS to differentiate between INIT and cold/warm reset.
- Determine the history of this reset using the [D18F0x6C](#) [[Link Initialization Control](#)] [[ColdRstDet](#)] bit:
  - If this is a warm reset then BIOS may check for valid MCA errors and if present save the status for use later. See [2.15.1.6 \[Handling Machine Check Exceptions\]](#).
- Set up the local APIC. See [2.4.9.1.3 \[ApicId Enumeration Requirements\]](#).
- Configure processor power management. See [2.4 \[Core\]](#).

### 2.3.3 Using L2 Cache as General Storage During Boot

Prior to initializing the DRAM controller for system memory, BIOS may use the L2 cache of each core as general storage.

The L2 cache as general storage is described as follows:

- Each Compute Unit has its own L2 cache.
- BIOS manages the mapping of the L2 storage such that cacheable accesses do not cause L2 victims.
- The L2 size, L2 associativity, and L2 line size is determined by reading [CPUID Fn8000\\_0006\\_ECX](#)[L2Size, L2Assoc, L2LineSize]. L2WayNum is defined to be the number of ways indicated by the L2Assoc code.
  - The L2 cache is viewed as (L2Size/L2LineSize) cache lines of storage, organized as L2WayNum ways, each way being (L2Size/L2WayNum) in size.
    - E.g. L2Assoc=8 so L2WayNum=16 (there are 16 ways). If (L2Size=2MB) then there are 16 blocks of cache, each 2MB/16 in size, or 128KB each.
  - For each of the following values of L2Size, the following values are defined:

- L2Size=1 MB: L2Tag=PhysAddr[39:16], L2WayIndex=PhysAddr[15:6].
- L2Size=2 MB: L2Tag=PhysAddr[39:17], L2WayIndex=PhysAddr[16:6].
- PhysAddr[5:0] addresses the L2LineSize number of bytes of storage associated with the cache line.
- The L2 cache, when allocating a line at L2WayIndex:
  - Picks an invalid way before picking a valid way.
  - Prioritizes the picking of invalid ways such that way L2WayNum-1 is the highest priority and 0 is the lowest priority.
- It is recommended that BIOS assume a simpler allocation of L2 cache memory, being L2WayNum size-aligned blocks of memory, each being L2Size/L2WayNum bytes.
- BIOS can rely on a minimum L2Size of 256 KB and can rely on being able to use a minimum of 14 ways for general storage. See [CPUID Fn8000\\_0006\\_ECX\[L2Size\]](#). See initialization requirements below for [MSRC001\\_1023\[L2WayLock, L2FirstLockedWay\]](#).

The following memory types are supported:

- WP-IO: BIOS ROM may be assigned the write-protect IO memory type and may be accessed read-only as data and fetched as instructions.
  - WP-IO accesses, both read and write, do not get evicted to the L2 and therefore do not need to be considered for allocation into the L2.
- WB-DRAM: General storage may be assigned the write-back DRAM memory type and may be accessed as read-write data, but not accessed by instruction fetch.
  - BIOS initializes an L2LineSize sized and aligned location in the L2 cache, mapped as write-back DRAM, with 1 read to at least 1 byte of the L2LineSize sized and aligned WB-DRAM address. BIOS may store to a line only after it has been allocated by a load.
  - Fills, sent to the disabled memory controller, return undefined data.
- All of memory space that is not accessed as WP-IO or WB-DRAM space must be marked as UC memory type.
- In order to prevent victimizing L2 data, no more than L2WayNum cache lines accessed as WB-DRAM may have the same L2WayIndex.
  - Software does not need to know which ways the L2WayNum lines are allocated to for any given value of L2WayIndex, only that invalid ways will be selected for allocation before valid ways will be selected for allocation.
  - Software is not allowed to deallocate a line in the L2 by using CLFLUSH.

Performance monitor event [PMCx07F\[1\]](#), titled “L2 Writebacks to system“, can be used to indicate whether L2 dirty data was lost by being victimized and sent to the disabled memory controller.

The following requirements must be satisfied prior to using the cache as general storage:

- Paging must be disabled.
- [MSRC001\\_0015\[INVDWBINVD\]](#)=0.
- [MSRC001\\_1020\[DisSS\]](#)=1.
- [MSRC001\\_1021\[DisSpecTlbRld\]](#)=1. Disable speculative ITLB reloads.
- [MSRC001\\_1022\[DisSpecTlbRld\]](#)=1. Disable speculative DTLB reloads.
- [MSRC001\\_1022\[DisHwPf\]](#)=1.
- [MSRC001\\_102B\[CombineCr0Cd\]](#)=0. See [MSRC001\\_102B\[CombineCr0Cd\]](#).
- CLFLUSH, INVD, and WBINVD must not be used during [CAR](#) but may be used when tearing down [CAR](#) for all compute units on a node.
- The BIOS must not use SSE, or MMX™ instructions, with the exception of the following list: MOVD, MOVQ, MOVDQA, MOVQ2DQ, MOVDQ2Q.
- The BIOS must not enable exceptions, page-faults, and other interrupts.
- BIOS must not use software prefetches.

- UC-DRAM: All of DRAM that is not accessed as WB-DRAM space must be marked as UC memory type.
- If (`MSRC001_1023[L2WayLock]==1`) then:
  - Only the ways 0 through (`MSRC001_1023[L2FirstLockedWay]-1`) may be used for general storage.
  - BIOS can rely on `MSRC001_1023[L2FirstLockedWay]` to have a minimum value of Eh.
- If (`MSRC001_1023[L2WayLock]==0`) then:
  - Set `MSRC001_1023[L2WayLock]=1`.
  - Set `MSRC001_1023[L2FirstLockedWay]=Fh`.

When BIOS has completed using the cache for general storage the following steps are followed:

1. An INVD instruction is executed on each core that used cache as general storage; an INVD is issued when all cores on all nodes have completed using the cache for general storage.
2. If DRAM is initialized and there is data in the cache that needs to get moved to main memory, CLFLUSH or WBINVD may be used instead of INVD, but software must ensure that needed data in main memory is not overwritten.
3. Program the following configuration state (Order is unimportant):
  - `MSRC001_0015[INVDWBINVD]=1`.
  - `MSRC001_1020[DisSS]=0`.
  - `MSRC001_1021[DisSpecTlbRld]=0`.
  - `MSRC001_1022[DisSpecTlbRld]=0`.
  - `MSRC001_1022[DisHwPf]=0`.
  - If (`((MSRC001_1023[L2WayLock]==1) & (MSRC001_1023[L2FirstLockedWay]==Fh))`), program `MSRC001_1023[L2WayLock]=0`.

## 2.4 Core

The majority of the behavioral definition of the core is specified in the AMD64 Architecture Programmer's Manual. See [1.2 \[Reference Documents\]](#).

### 2.4.1 Compute Unit

Each *compute unit* includes 2 cores each having an x86 instruction execution logic and first-level (L1) data cache. The FP unit, second level (L2) general-purpose cache, and first-level instruction cache, are shared between both cores of the compute unit.

There is a set of MSRs and APIC registers associated with each core. Processors that include multiple cores are said to incorporate *chip multi-processing* or CMP. Unless otherwise specified the processor configuration interface hides the Compute Unit implementation and presents software with homogenous cores, each independent of the other.

Software may use `D18F5x80[Enabled, DualCore]` in order to associate a core with a Compute Unit. This information can be useful because some configuration settings are determined based on active Compute Units and core performance may vary based on resource sharing within a Compute Unit.

**Table 6: Compute Unit Definitions**

Term	Definition
<b>NumOfCompUnits</b>	The number of compute units for which at least 1 core is enabled. <code>NumOfCompUnits = COUNT(D18F5x80[Enabled])</code> .
<b>DualCoreEnabled</b>	Both cores of a compute unit are enabled. <code>DualCoreEnabled = (D18F5x80[DualCore[0]]==1)</code> . 0=Core 0 enabled, Core 1 disabled.

## 2.4.2 Caches and TLBs

Cache and TLB storage available to a core is reported by:

- [CPUID Fn8000\\_0005\\_EAX](#)-[CPUID Fn8000\\_0006\\_EDX](#).
- [CPUID Fn8000\\_0019\\_EAX](#)-[CPUID Fn8000\\_0019\\_E\[D,C\]X](#).
- [CPUID Fn8000\\_001D\\_EAX\\_x0](#)-[CPUID Fn8000\\_001E\\_EDX](#).

Cache and TLB storage available to a core is summarized as follows:

- L1 and L2 Caches:
  - DC: 16 KB, 4-way, write-through, per-core.
  - IC: 96 KB, 2-way, shared between cores of a compute unit.
  - L2: 1 MB or 2MB (Product-specific), 16-way associative, shared between both cores of a compute unit.
- TLBs:
  - D, L1TLB:
    - 4 KB: 32 entries, fully associative.
    - 2 MB: 32 entries, fully associative.
    - 1 GB: 32 entries, fully associative.
  - D, L2TLB:
    - None. Full size of unified TLB reported as L2 DTLB.
  - I, L1TLB:
    - 4 KB: 48 entries, fully associative.
    - 2 MB, 1 GB: 24 entries, fully associative. 2M and 1G entries share the same L1TLB bank.
  - I, L2TLB:
    - 4 KB: 512 entries, 4-way associative. (Same as Fam10h)
    - 2 MB: None. Full size of unified TLB reported as L2 ITLB.
    - 1 GB: None. Full size of unified TLB reported as L2 ITLB.
  - Unified TLB:
    - 1024 entries, 8-way associative, any entry can cache:
      - D: 4K, 2M, 4M, or 1G translation.
      - I: 2M, 4M, or 1G translation. Not 4K ITLB translations.
      - Notes: Unified TLB natively stores 4M translations. An entry allocated by one core is not visible to the other core of a compute unit.

### 2.4.2.1 Registers Shared by Cores in a Compute Unit

Some registers are implemented one instance per Compute Unit instead of per core; these registers are designated as [Per-compute-unit](#). The absence of [Per-compute-unit](#) implies the normal per-core instance programming model.

Some [Per-compute-unit](#) MSRs are implemented as registers that when read the contents are saved in the L1 data cache and are not coherent between cores; these registers are called [SharedNC](#) or “shared non-coherent”.

Programming rules for [Per-compute-unit](#) registers:

- Software must ensure that a shared MSR written by one core on a Compute Unit will not cause a problem for software that is running on the other core of the Compute Unit.
- Not [SharedNC](#): A write to a MSR does not have to be written to the other core of the compute unit in order for the other core to see the updated value.
- [SharedNC](#): A write to a [SharedNC](#) MSR has to be written to both cores of the compute unit in order for both cores to see the updated value.
  - If software can know that the other core has not read the [SharedNC](#) MSR since the last warm reset, then a write is not needed to the [SharedNC](#) MSR on the other core.
  - Software may not rely on the other core maintaining the previous value of the [SharedNC](#) MSR.

- The [SharedNC](#) MSRs are: [MSRC001\\_00\[35:30\]](#), [MSRC001\\_0054](#).
- A read-modify-write of a shared MSR register is not atomic. Software must ensure atomicity between the cores that could simultaneously read-modify-write the shared register.

### 2.4.3 Virtual Address Space

The processor supports 48 address bits of virtual memory space (256 TB) as indicated by [CPUID Fn8000\\_0008\\_EAX](#).

### 2.4.4 Processor Cores and Downcoring

Each node supports downcoring as follows:

- The number of cores supported is specified by [D18F5x84\[CmpCap\]](#).
- The cores of a compute unit may be software downcored by [D18F3x190\[DisCore\]](#) if ([DualCoreEnabled](#)==1). If ([DualCoreEnabled](#)==0) then the cores of a compute unit may not be software downcored. See [2.4.4.1 \[Software Downcoring using D18F3x190\[DisCore\]\]](#).
  - All cores of a compute unit must be downcored if either core needs to be downcored.
  - Clocks are turned off and power is gated to downcored Compute Units. The power savings is the same as CC6.
  - There must be at least 1 Compute Unit enabled.
  - [D18F3x190\[DisCore\]](#) affects the value of [CPUID Fn0000\\_0001\\_EBX\[LogicalProcessorCount\]](#), [CPUID Fn0000\\_0001\\_EDX\[HTT\]](#), [CPUID Fn8000\\_0001\\_ECX\[CmpLegacy\]](#), [CPUID Fn8000\\_0008\\_ECX\[NC\]](#), [D18F5x80\[Enabled, DualCore\]](#). [D18F3x190\[DisCore\]](#) does not affect the value of [D18F5x84\[CmpCap\]](#).
- An implemented (physical) core that is downcored is not visible to software. Cores that are not downcored are numbered logically in a contiguous manner.
- [D18F5x80 \[Compute Unit Status 1\]](#) reports core topology information to software.
- The number of cores specified in [CPUID Fn8000\\_0008\\_ECX\[NC\]](#) must be the same as the number of cores enabled in [D18F0x1DC\[CpuEn\]](#).
- The core number, *CpuCoreNum*, is provided to SW running on each core through [CPUID Fn0000\\_0001\\_EBX\[LocalApicId\]](#) and [APIC20\[ApicId\]](#); *CpuCoreNum* also affects [D18F0x1DC\[CpuEn\]](#). *CpuCoreNum*, varies as the lowest integers from 0 to [D18F5x84\[CmpCap\]](#), based on the number of enabled cores; e.g., a 4-core node with 1 core disabled results in cores reporting *CpuCoreNum* values of 0, 1, and 2 regardless of which core is disabled. The boot core is always the core reporting *CpuCoreNum*=0.

Some legacy operating systems do not support processors with a non-power-of-2 number of cores. The BIOS is recommended to support a user configurable option to disable cores down to a power-of-2 number of cores for legacy operating system support.

#### 2.4.4.1 Software Downcoring using D18F3x190[DisCore]

Cores may be downcored by [D18F3x190\[DisCore\]](#).

Software is required to use [D18F3x190\[DisCore\]](#) as follows:

- Setting bits corresponding to cores that are not present results in undefined behavior.
- Once a core has been removed by [D18F3x190\[DisCore\]=1](#), it cannot be added back without a cold reset. E.g. Software may only set *DisCore* bits, never clear them.
- Software may remove cores only once. If software removes cores by setting [D18F3x190\[DisCore\]=1](#), then software is not allowed to disable additional cores after the next warm reset.
- The most significant bit N is (the number of cores)-1 at cold reset; the number of cores at cold reset is ([CPUID Fn8000\\_0008\\_ECX\[NC\]](#)+1).

- The most significant bit N and the core ID significance of DisCore is not affected by the value of DisCore followed by a warm-reset.
  - E.g. If core 2 is disabled by DisCore[3:0]=0100b followed by a warm reset, then the new core 2 is the old core 3. If the new core 2 needs to then be disabled then DisCore[3:0]=1100b followed by a warm reset.
- All bits greater than bit N are reserved.
- If D18F3x190[DisCore] is changed, then the following need to be updated:
  - D18F0x60[CpuCnt[4:0]].
  - D18F5x170[NbPstateThreshold]
  - MSRC001\_102A[ThrottleNbInterface]

### 2.4.5 Physical Address Space

The processor supports a 40 bit physical address space, even though the core indicates support for a 48 bit physical address space. See CPUID Fn8000\_0008\_EAX [Long Mode Address Size Identifiers].

The processor master aborts the following upper-address transactions (to address PhysAddr):

- Link or core requests with non-zero PhysAddr[63:40].

### 2.4.6 System Address Map

The processor defines a reserved memory address region starting at 0000\_00FD\_0000\_0000h and extending up to 0000\_0100\_0000\_0000h. System software must not map memory into this region. Downstream host accesses to the reserved address region results in a page fault. Upstream system device accesses to the reserved address region results in an undefined operation.

#### 2.4.6.1 Memory Access to the Physical Address Space

All memory accesses to the physical address space from a core are sent to its associated northbridge (NB). All memory accesses from a link are routed through the NB. An IO link access to physical address space indicates to the NB the cache attribute (Coherent or Non-coherent, based on bit[0] of the Sized Read and Write commands).

A core access to physical address space has two important attributes that must be determined before issuing the access to the NB: the memory type (e.g., WB, WC, UC; as described in the MTRRs) and the access destination (DRAM or MMIO).

This mechanism is managed by the BIOS and does not require any setup or changes by system software.

##### 2.4.6.1.1 Determining Memory Type

The memory type for a core access is determined by the highest priority of the following ranges that the access falls in: 1==Lowest priority.

1. The memory type as determined by architectural mechanisms.
  - See the APM2 chapter titled “Memory System”, sections “Memory-Type Range Registers” and “Page-Attribute Table Mechanism”.
  - See the APM2 chapter titled “Nested Paging”, section “Combining Memory Types, MTRRs”.
  - See MSR0000\_02FF [MTRR Default Memory Type (MTRRdefType)], MSR0000\_020[F:0] [Variable-Size MTRRs Base/Mask], MSR0000\_02[6F:68,59:58,50] [Fixed-Size MTRRs].
2. TSeg & ASeg SMM mechanism. (see MSRC001\_0112 and MSRC001\_0113)
3. CR0[CD]: If (CR0[CD]==1) then MemType=CD.
4. MMIO config space, APIC space.

- MMIO APIC space and MMIO config space must not overlap.
  - MemType=UC.
  - See 2.4.9.1.2 [APIC Register Space] and 2.7 [Configuration Space].
5. If (“In SMM Mode” && ~((MSRC001\_0113[AValid] && “The address falls within the ASeg region”) || (MSRC001\_0113[TValid] && “The address falls within the TSeg region”))) then MemType=CD.

#### 2.4.6.1.2 Determining The Access Destination for Core Accesses

The access destination, DRAM or MMIO, is based on the highest priority of the following ranges that the access falls in: 1==Lowest priority.

1. RdDram/WrDram as determined by MSRC001\_001A [Top Of Memory (TOP\_MEM)] and MSRC001\_001D [Top Of Memory 2 (TOM2)].
2. The IORRs. (see MSRC001\_00[18,16] and MSRC001\_00[19,17]).
3. The fixed MTRRs. (see MSR0000\_02[6F:68,59:58,50] [Fixed-Size MTRRs])
4. TSeg & ASeg SMM mechanism. (see MSRC001\_0112 and MSRC001\_0113)
5. MMIO config space, APIC space.
  - MMIO APIC space and MMIO config space must not overlap.
  - RdDram=IO, WrDram=IO.
  - See 2.4.9.1.2 [APIC Register Space] and 2.7 [Configuration Space].
6. NB address space routing. See 2.8.2.1.1 [DRAM and MMIO Memory Space].

#### 2.4.7 Timers

Each core includes the following timers. These timers do not vary in frequency regardless of the current P-state or C-state.

- MSR0000\_0010 [Time Stamp Counter (TSC)]; the TSC increments at the rate specified by the P0 P-state.
  - See 2.5.3.1.1.1 [Software P-state Numbering].
  - See MSRC001\_00[6B:64] [P-state [7:0]].
- The APIC timer (APIC380 and APIC390), which increments at the rate of 2xCLKIN; the APIC timer may increment in units of between 1 and 8.

#### 2.4.8 Implicit Conditions for TLB Invalidation

The following family specific conditions will cause all TLBs for both cores of the compute unit to be invalidated; except MSR0000\_0277 which will only clear the TLBs for the core that did the MSR write. The architectural conditions that cause TLB invalidation are documented by the APM2 section titled “Translation-Lookaside Buffer (TLB)”; see “Implicit Invalidations”.

- MSR0000\_020[F:0] [Variable-Size MTRRs Base/Mask]
- MSR0000\_02[6F:68,59:58,50] [Fixed-Size MTRRs]
- MSR0000\_0277 [Page Attribute Table (PAT)] (TLBs not cleared for the other core)
- MSR0000\_02FF [MTRR Default Memory Type (MTRRdefType)]
- MSRC001\_0010 [System Configuration (SYS\_CFG)] write.
- MSRC001\_00[18,16] [IO Range Base (IORR\_BASE[1:0])] write.
- MSRC001\_00[19,17] [IO Range Mask (IORR\_MASK[1:0])] write.
- MSRC001\_001A [Top Of Memory (TOP\_MEM)] write.
- MSRC001\_001D [Top Of Memory 2 (TOM2)] write.
- MSRC001\_1023 [Combined Unit Configuration (CU\_CFG)] write.
- MSRC001\_102A [Combined Unit Configuration 2 (CU\_CFG2)] write.
- MSRC001\_102B [Combined Unit Configuration 3 (CU\_CFG3)] write.

## 2.4.9 Interrupts

### 2.4.9.1 Local APIC

The local APIC contains logic to receive interrupts from a variety of sources and to send interrupts to other local APICs, as well as registers to control its behavior and report status. Interrupts can be received from:

- IO devices including the IO hub (IO APICs)
- Other local APICs (inter-processor interrupts)
- APIC timer
- Thermal events
- Performance counters
- Legacy local interrupts from the IO hub (INTR and NMI)
- APIC internal errors

The APIC timer, thermal events, performance counters, local interrupts, and internal errors are all considered local interrupt sources, and their routing is controlled by local vector table entries. These entries assign a message type and vector to each interrupt, allow them to be masked, and track the status of the interrupt.

IO and inter-processor interrupts have their message type and vector assigned at the source and are unaltered by the local APIC. They carry a destination field and a mode bit that together determine which local APIC(s) accepts them. The destination mode (DM) bit specifies if the interrupt request packet should be handled in physical or logical destination mode. If the destination field matches the broadcast value specified by [D18F0x68](#)[ApicExtBrdCst], then the interrupt is a broadcast interrupt and is accepted by all local APICs regardless of destination mode.

#### 2.4.9.1.1 Detecting and Enabling

APIC is detected and enabled via [CPUID Fn0000\\_0001\\_EDX](#)[APIC].

The local APIC is enabled via [MSR0000\\_001B](#)[ApicEn]. Reset forces APIC disabled.

#### 2.4.9.1.2 APIC Register Space

MMIO APIC space:

- Memory mapped to a 4 KB range. The memory type of this space is the UC memory type. The base address of this range is specified by {[MSR0000\\_001B](#)[ApicBar[47:12]], 000h}.
- The mnemonic is defined to be APICXX; XX is the byte address offset from the base address.
- MMIO APIC registers in xAPIC mode is defined by the register from [APIC20](#) to [APIC\[530:500\]](#).
- Treated as normal memory space when APIC is disabled, as specified by [MSR0000\\_001B](#)[ApicEn].

#### 2.4.9.1.3 ApicId Enumeration Requirements

System hardware and BIOS must ensure that the number of cores per processor (NC) exposed to the operating system by all tables, registers, and instructions across all cores in the processor is identical. See [2.4.11.1 \[Multi-Core Support\]](#) to derive NC.

Operating systems are expected to use [CPUID Fn8000\\_0008\\_ECX](#)[ApicIdCoreIdSize], the number of least significant bits in the Initial APIC ID that indicate core ID within a processor, in constructing per-core CPUID masks. (ApicIdCoreIdSize[3:0] determines the maximum number of cores (MNC) that the processor could theoretically support, not the actual number of cores that are actually implemented or enabled on the processor, as indicated by [CPUID Fn8000\\_0008\\_ECX](#)[NC].)  $MNC = (2 \wedge \text{CPUID Fn8000\_0008\_ECX}[\text{ApicIdCoreIdSize}])$ .

BIOS must use the ApicId MNC rule when assigning [APIC20\[ApicId\]](#) values as described below.

ApicId MNC rule: The ApicId of core j on processor i must be enumerated/assigned as:

- $\text{ApicId}[\text{proc}=i, \text{core}=j] = (\text{OFFSET\_IDX} + i) * \text{MNC} + j$
- Where OFFSET\_IDX is an integer offset (0 to N) used to shift up the core ApicId values to allow room for IOAPIC devices.

It is recommended that BIOS use the following APIC ID assignments for the broadest operating system support. Given  $N = (\text{Number\_Of\_Processors} * \text{MNC})$  and  $M = \text{Number\_Of\_IOAPICs}$ :

- If  $(N+M) < 16$ , then assign the local (core) ApicIds first from 0 to N-1, and the IOAPIC IDs from N to N+(M-1). APIC ID 15 is reserved for broadcast when [APIC410\[ExtApicIdEn\]](#)==0.
- If  $(N+M) \geq 16$ , then assign the IOAPIC IDs first from 0 to M-1, and the local (core) ApicIds from K to K+(N-1), where K is an integer multiple of MNC greater than M-1.

#### 2.4.9.1.4 Physical Destination Mode

The interrupt is only accepted by the local APIC whose [APIC20\[ApicId\]](#) matches the destination field of the interrupt. Physical mode allows up to 255 APICs to be addressed individually.

#### 2.4.9.1.5 Logical Destination Mode

A local APIC accepts interrupts selected by [APICD0 \[Logical Destination \(LDR\)\]](#) and the destination field of the interrupt using either cluster or flat format as configured by [APICE0\[Format\]](#).

If flat destinations are in use, bits 7-0 of [APICD0\[Destination\]](#) are checked against bits 7-0 of the arriving interrupt's destination field. If any bit position is set in both fields, the local APIC is a valid destination. Flat format allows up to 8 APICs to be addressed individually.

If cluster destinations are in use, bits 7-4 of [APICD0\[Destination\]](#) are checked against bits 7-4 of the arriving interrupt's destination field to identify the cluster. If all of bits 7-4 match, then bits 3-0 of [APICD0\[Destination\]](#) and the interrupt destination are checked for any bit positions that are set in both fields to identify processors within the cluster. If both conditions are met, the local APIC is a valid destination. Cluster format allows 15 clusters of 4 APICs each to be addressed.

#### 2.4.9.1.6 Interrupt Delivery

SMI, NMI, INIT, Startup, and External interrupts are classified as non-vectorized interrupts.

When an APIC accepts a non-vectorized interrupt, it is handled directly by the processor instead of being queued in the APIC. When an APIC accepts a fixed or lowest-priority interrupt, it sets the bit in [APIC\[270:200\] \[Interrupt Request \(IRR\)\]](#) corresponding to the vector in the interrupt. For local interrupt sources, this comes from the vector field in that interrupt's local vector table entry. The corresponding bit in [APIC\[1F0:180\] \[Trigger Mode \(TMR\)\]](#) is set if the interrupt is level-triggered and cleared if edge-triggered. If a subsequent interrupt with the same vector arrives when the corresponding bit in [APIC\[270:200\]\[RequestBits\]](#) is already set, the two interrupts are collapsed into one. Vectors 15-0 are reserved.

#### 2.4.9.1.7 Vectored Interrupt Handling

[APIC80 \[Task Priority \(TPR\)\]](#) and [APICA0 \[Processor Priority \(PPR\)\]](#) each contain an 8-bit priority divided into a main priority (bits 7-4) and a priority sub-class (bits 3-0). The task priority is assigned by software to set a threshold priority at which the processor is interrupted.

The processor priority is calculated by comparing the main priority (bits 7-4) of [APIC80\[Priority\]](#) to bits 7-4 of the 8-bit encoded value of the highest bit set in [APIC\[170:100\] \[In-Service \(ISR\)\]](#). The processor priority is the higher of the two main priorities.

The processor priority is used to determine if any accepted interrupts (indicated by [APIC\[270:200\]\[Request-Bits\]](#)) are high enough priority to be serviced by the processor. When the processor is ready to service an interrupt, the highest bit in [APIC\[270:200\]\[RequestBits\]](#) is cleared, and the corresponding bit is set in [APIC\[170:100\]\[InServiceBits\]](#).

When the processor has completed service for an interrupt, it performs a write to [APICB0 \[End of Interrupt\]](#), clearing the highest bit in [APIC\[170:100\]\[InServiceBits\]](#) and causing the next-highest interrupt to be serviced. If the corresponding bit in [APIC\[1F0:180\]\[TriggerModeBits\]](#) is set, a write to [APICB0](#) is performed on all APICs to complete service of the interrupt at the source.

#### 2.4.9.1.8 Interrupt Masking

Interrupt masking is controlled by the [APIC410 \[Extended APIC Control\]](#). If [APIC410\[IerEn\]](#) is set, [APIC\[4F0:480\] \[Interrupt Enable\]](#) are used to mask interrupts. Any bit in [APIC\[4F0:480\]\[InterruptEnableBits\]](#) that is clear indicates the corresponding interrupt is masked. A masked interrupt is not serviced and the corresponding bit in [APIC\[270:200\]\[RequestBits\]](#) remains set.

#### 2.4.9.1.9 Spurious Interrupts

In the event that the task priority is set to or above the level of the interrupt to be serviced, the local APIC delivers a spurious interrupt vector to the processor, as specified by [APICF0 \[Spurious-Interrupt Vector \(SVR\)\]](#). [APIC\[170:100\]](#) is not changed and no write to [APICB0](#) occurs.

#### 2.4.9.1.10 Spurious Interrupts Caused by Timer Tick Interrupt

A typical interrupt is asserted until it is serviced. An interrupt is deasserted when software clears the interrupt status bit within the interrupt service routine. Timer tick interrupt is an exception, since it is deasserted regardless of whether it is serviced or not.

The processor is not always able to service interrupts immediately (i.e. when interrupts are masked by clearing [EFLAGS.IM](#)).

If the processor is not able to service the timer tick interrupt for an extended period of time, the INTR caused by the first timer tick interrupt asserted during that time is delivered to the local APIC in ExtInt mode and latched, and the subsequent timer tick interrupts are lost. The following cases are possible when the processor is ready to service interrupts:

- An ExtInt interrupt is pending, and INTR is asserted. This results in timer tick interrupt servicing. This occurs 50 percent of the time.
- An ExtInt interrupt is pending, and INTR is deasserted. The processor sends the interrupt acknowledge cycle, but when the PIC receives it, INTR is deasserted, and the PIC sends a spurious interrupt vector. This occurs 50 percent of the time.

There is a 50 percent probability of spurious interrupts to the processor.

#### 2.4.9.1.11 Lowest-Priority Interrupt Arbitration

Fixed, remote read, and non-vectored interrupts are accepted by their destination APICs without arbitration.

Delivery of lowest-priority interrupts requires all APICs to arbitrate to determine which one accepts the interrupt. If [APICF0\[FocusDisable\]](#) is clear, then the focus processor for an interrupt always accepts the interrupt. A processor is the focus of an interrupt if it is already servicing that interrupt (corresponding bit in [APIC\[170:100\]\[InServiceBits\]](#) is set) or if it already has a pending request for that interrupt (corresponding bit in [APIC\[270:200\]\[RequestBits\]](#) is set). If [APIC410\[IerEn\]](#) is set the interrupt must also be enabled in [APIC\[4F0:480\]\[InterruptEnableBits\]](#) for a processor to be the focus processor. If there is no focus processor for an interrupt, or focus processor checking is disabled, then each APIC calculates an arbitration priority value, stored in [APIC90 \[Arbitration Priority \(APR\)\]](#), and the one with the lowest result accepts the interrupt.

The arbitration priority value is calculated by comparing [APIC80\[Priority\]](#) with the 8-bit encoded value of the highest bit set in [APIC\[270:200\]\[RequestBits\]](#) (IRRVec) and the 8-bit encoded value of the highest bit set [APIC\[170:100\]\[InServiceBits\]](#) (ISRVec). If [APIC410\[IerEn\]](#) is set the IRRVec and ISRVec are based off the highest enabled interrupt. The main priority bits 7-4 are compared as follows:

```
IF ((APIC80[Priority[7:4]] >= IRRVec[7:4]) && (APIC80[Priority[7:4]] > ISRVec[7:4])) THEN
    APIC90[Priority] = APIC80[Priority]
ELSEIF (IRRVec[7:4] > ISRVec[7:4]) THEN
    APIC90[Priority] = {IRRVec[7:4],0h}
ELSE
    APIC90[Priority] = {ISRVec[7:4],0h}
ENDIF.
```

#### 2.4.9.1.12 Inter-Processor Interrupts

[APIC300 \[Interrupt Command Low \(ICR Low\)\]](#) and [APIC310 \[Interrupt Command High \(ICR High\)\]](#) provide a mechanism for generating interrupts in order to redirect an interrupt to another processor, originate an interrupt to another processor, or allow a processor to interrupt itself. A write to register [APIC300](#) causes an interrupt to be generated with the properties specified by the [APIC300](#) and [APIC310](#) fields.

#### 2.4.9.1.13 APIC Timer Operation

The local APIC contains a 32-bit timer, controlled by [APIC320 \[LVT Timer\]](#), [APIC380 \[Timer Initial Count\]](#), and [APIC3E0 \[Timer Divide Configuration\]](#). The processor bus clock is divided by the value in [APIC3E0\[Div\]](#) to obtain a time base for the timer. When [APIC380\[Count\]](#) is written, the value is copied into [APIC390 \[Timer Current Count\]](#). [APIC390\[Count\]](#) is decremented at the rate of the divided clock. When the count reaches 0, a timer interrupt is generated with the vector specified in [APIC320\[Vector\]](#). If [APIC320\[Mode\]](#) specifies periodic operation, [APIC390\[Count\]](#) is reloaded with the [APIC380\[Count\]](#) value, and it continues to decrement at the rate of the divided clock. If [APIC320\[Mask\]](#) is set, timer interrupts are not generated.

#### 2.4.9.1.14 Generalized Local Vector Table

All LVTs ([APIC330](#) to [APIC3\[60:50\]](#), and [APIC\[530:500\]](#)) support a generalized message type as follows:

- 000b=Fixed
- 010b=SMI
- 100b=NMI
- 111b=ExtINT
- All other messages types are reserved.

#### 2.4.9.1.15 State at Reset

At power-up or reset, the APIC is hardware disabled ([MSR0000\\_001B\[ApicEn\]=0](#)) so only SMI, NMI, INIT, and ExtInt interrupts may be accepted.

The APIC can be software disabled through [APICF0\[APICSWEn\]](#). The software disable has no effect when the APIC is hardware disabled.

When a processor accepts an INIT interrupt, the APIC is reset as at power-up, with the exception that:

- [APIC20\[ApicId\]](#) is unaffected.
- Pending APIC register writes complete.

## 2.4.9.2 System Management Mode (SMM)

System management mode (SMM) is typically used for system control activities such as power management. These activities are typically transparent to the operating system.

### 2.4.9.2.1 SMM Overview

SMM is entered by a core on the next instruction boundary after a system management interrupt (SMI) is received and recognized. A core may be programmed to broadcast a special cycle to the system, indicating that it is entering SMM mode. The core then saves its state into the SMM memory state save area and jumps to the SMI service routine (or SMI handler). The pointer to the SMI handler is specified by MSRs. The code and data for the SMI handler are stored in the SMM memory area, which may be isolated from the main memory accesses.

The core returns from SMM by executing the RSM instruction from the SMI handler. The core restores its state from the SMM state save area and resumes execution of the instruction following the point where it entered SMM. The core may be programmed to broadcast a special bus cycle to the system, indicating that it is exiting SMM mode.

### 2.4.9.2.2 Operating Mode and Default Register Values

The software environment after entering SMM has the following characteristics:

- Addressing and operation is in Real mode.
  - A far jump, call or return in the SMI handler can only address the lower 1M of memory, unless the SMI handler first switches to protected mode.
  - If ([MSRC001\\_0111\[SmmBase\]](#) >= 0010\_0000h) then:
    - The value of the CS selector is undefined upon SMM entry.
    - The undefined CS selector value should not be used as the target of a far jump, call, or return.
- 4-Gbyte segment limits.
- Default 16-bit operand, address, and stack sizes (instruction prefixes can override these defaults).
- Control transfers that do not override the default operand size truncate the EIP to 16 bits.
- Far jumps or calls cannot transfer control to a segment with a base address requiring more than 20 bits, as in Real mode segment-base addressing, unless a change is made into protected mode.
- A20M# is disabled. A20M# assertion or deassertion have no affect during SMM.
- Interrupt vectors use the Real mode interrupt vector table.
- The IF flag in EFLAGS is cleared (INTR is not recognized).
- The TF flag in EFLAGS is cleared.
- The NMI and INIT interrupts are masked.
- Debug register DR7 is cleared (debug traps are disabled).

The SMM base address is specified by [MSRC001\\_0111\[SmmBase\]](#). Important offsets to the base address pointer are:

- [MSRC001\\_0111\[SmmBase\]](#) + 8000h: SMI handler entry point.
- [MSRC001\\_0111\[SmmBase\]](#) + FE00h - FFFFh: SMM state save area.

### 2.4.9.2.3 SMI Sources And Delivery

The processor accepts SMIs as link-defined interrupt messages only. The core/node destination of these SMIs is a function of the destination field of these messages. However, the expectation is that all such SMI messages are specified to be delivered globally (to all cores of all nodes).

There are also several local events that can trigger SMIs. However, these local events do not generate SMIs directly. Each of them triggers a programmable IO cycle that is expected to target the SMI command port in the IO hub and trigger a global SMI interrupt message back to the coherent fabric.

Local sources of SMI events that generate the IO cycle specified in [MSRC001\\_0056 \[SMI Trigger IO Cycle\]](#) are:

- In the core, as specified by:
  - [MSRC001\\_0022 \[Machine Check Exception Redirection\]](#).
  - [MSRC001\\_00\[53:50\] \[IO Trap \(SMI\\_ON\\_IO\\_TRAP\\_\[3:0\]\)\]](#).
- All local APIC LVT registers programmed to generate SMIs.

The status for these is stored in [SMMFEC4](#).

### 2.4.9.2.4 SMM Initial State

After storing the save state, execution starts at [MSRC001\\_0111\[SmmBase\]](#) + 08000h. The SMM initial state is specified in the following table.

**Table 7: SMM Initial State**

Register	SMM Initial State
CS	SmmBase[19:4]
DS	0000h
ES	0000h
FS	0000h
GS	0000h
SS	0000h
General-Purpose Registers	Unmodified
EFLAGS	0000_0002h
RIP	0000_0000_0000_8000h
CR0	Bits 0, 2, 3, and 31 cleared (PE, EM, TS, and PG); remainder is unmodified
CR4	0000_0000_0000_0000h
GDTR	Unmodified
LDTR	Unmodified
IDTR	Unmodified
TR	Unmodified
DR6	Unmodified
DR7	0000_0000_0000_0400h
EFER	All bits are cleared except bit 12 (SVME) which is unmodified.

### 2.4.9.2.5 SMM Save State

In the following table, the offset field provides the offset from the SMM base address specified by [MSRC001\\_0111 \[SMM Base Address \(SMM\\_BASE\)\]](#).

**Table 8: SMM Save State**

Offset	Size	Contents		Access
FE00h	Word	ES	Selector	Read-only
FE02h	6 Bytes		Reserved	
FE08h	Quadword		Descriptor in memory format	
FE10h	Word	CS	Selector	Read-only
FE12h	6 Bytes		Reserved	
FE18h	Quadword		Descriptor in memory format	
FE20h	Word	SS	Selector	Read-only
FE22h	6 Bytes		Reserved	
FE28h	Quadword		Descriptor in memory format	
FE30h	Word	DS	Selector	Read-only
FE32h	6 Bytes		Reserved	
FE38h	Quadword		Descriptor in memory format	
FE40h	Word	FS	Selector	Read-only
FE42h	2 Bytes		Reserved	
FE44h	Doubleword		FS Base {16'b[47], 47:32} <sup>1</sup>	
FE48h	Quadword		Descriptor in memory format	
FE50h	Word	GS	Selector	Read-only
FE52h	2 Bytes		Reserved	
FE54h	Doubleword		GS Base {16'b[47], 47:32} <sup>1</sup>	
FE58h	Quadword		Descriptor in memory format	
FE60h	4 Bytes	GDTR	Reserved	Read-only
FE64h	Word		Limit	
FE66h	2 Bytes		Reserved	
FE68h	Quadword		Descriptor in memory format	
FE70h	Word	LDTR	Selector	Read-only
FE72h	Word		Attributes	
FE74h	Doubleword		Limit	
FE78h	Quadword		Base	
FE80h	4 Bytes	IDTR	Reserved	Read-only
FE84h	Word		Limit	
FEB6h	2 Bytes		Reserved	
FE88h	Quadword		Base	

**Table 8: SMM Save State**

Offset	Size	Contents		Access
FE90h	Word	TR	Selector	Read-only
FE92h	Word		Attributes	
FE94h	Doubleword		Limit	
FE98h	Quadword		Base	
FEA0h	Quadword	IO_RESTART_RIP		Read-only
FEA8h	Quadword	IO_RESTART_RCX		
FEB0h	Quadword	IO_RESTART_RSI		
FEB8h	Quadword	IO_RESTART_RDI		
FEC0h	Doubleword	SMMFEC0 [SMM IO Trap Offset]		Read-only
FEC4	Doubleword	SMMFEC4 [Local SMI Status]		Read-only
FEC8h	Byte	SMMFEC8 [SMM IO Restart Byte]		Read-write
FEC9h	Byte	SMMFEC9 [Auto Halt Restart Offset]		Read-write
FECAh	Byte	SMMFECA [NMI Mask]		Read-write
FECBh	5 Bytes	Reserved

FFD8h	Quadword	RSP	
FFE0h	Quadword	RBX	
FFE8h	Quadword	RDX	
FFF0h	Quadword	RCX	
FFF8h	Quadword	RAX	

Notes:

1. This notation specifies that bit[47] is replicated in each of the 16 MSBs of the DW (sometimes called *sign extended*). The 16 LSB's contain bits[47:32].
2. Only used for an SMI in guest mode with nested paging enabled.

The SMI save state includes most of the integer execution unit. Not included in the save state are: the floating point state, MSRs, and CR2. In order to be used by the SMI handler, these must be saved and restored. The save state is the same, regardless of the operating mode (32-bit or 64-bit).

The following are some offsets in the SMM save state area. The mnemonic for each offset is in the form SMMxxxx, where xxxx is the offset in the save state.

### SMMFEC0 SMM IO Trap Offset

If the assertion of SMI is recognized on the boundary of an IO instruction, [SMMFEC0 \[SMM IO Trap Offset\]](#) contains information about that IO instruction. For example, if an IO access targets an unavailable device, the system can assert SMI and trap the IO instruction. [SMMFEC0](#) then provides the SMI handler with information about the IO instruction that caused the trap. After the SMI handler takes the appropriate action, it can reconstruct and then re-execute the IO instruction from SMM. Or, more likely, it can use [SMMFEC8 \[SMM IO Restart Byte\]](#), to cause the core to re-execute the IO instruction immediately after resuming from SMM.

Bits	Description
31:16	<b>Port: trapped IO port address.</b> Read-only. This provides the address of the IO instruction.
15:12	<b>BPR: IO breakpoint match.</b> Read-only.
11	<b>TF: EFLAGS TF value.</b> Read-only.

10:7	Reserved.
6	<b>SZ32: size 32 bits.</b> Read-only. 1=Port access was 32 bits.
5	<b>SZ16: size 16 bits.</b> Read-only. 1= Port access was 16 bits.
4	<b>SZ8: size 8 bits.</b> Read-only. 1=Port access was 8 bits.
3	<b>REP: repeated port access.</b> Read-only.
2	<b>STR: string-based port access.</b> Read-only.
1	<b>V: IO trap word valid.</b> Read-only. 1=The core entered SMM on an IO instruction boundary; all information in this offset is valid. 0=The other fields of this offset are not valid.
0	<b>RW: port access type.</b> Read-only. 0=IO write (OUT instruction). 1=IO read (IN instruction).

### SMMFEC4 Local SMI Status

This offset stores status bits associated with SMI sources local to the core. For each of these bits, 1=The associated mechanism generated an SMI.

Bits	Description
31:20	Reserved.
19	<b>SmiSrcThrCntHt: SMI source link thresholding.</b> Read-only. This bit is associated with the SMI source specified in the link thresholding register (see <a href="#">MSR0000_0403 [MC0 Machine Check Miscellaneous (MC0_MISC)]</a> ).
18	<b>SmiSrcThrCntDram: SMI source DRAM thresholding.</b> Read-only. This bit is associated with the SMI source specified in the DRAM thresholding register (see <a href="#">D18F3x160 [NB Machine Check Misc (DRAM Thresholding) 0 (MC4_MISC0)]</a> ).
17	<b>SmiSrcLvtExt: SMI source LVT extended entry.</b> Read-only. This bit is associated with the SMI sources specified in <a href="#">APIC[530:500] [Extended Interrupt [3:0] Local Vector Table]</a> .
16	<b>SmiSrcLvtLcy: SMI source LVT legacy entry.</b> Read-only. This bit is associated with the SMI sources specified by the non-extended LVT entries of the APIC.
15:11	Reserved.
10	<b>IntPendSmiSts: interrupt pending SMI status.</b> Read-only. This bit is associated with the SMI source specified when ( <a href="#">MSRC001_0055[IntPndMsg]</a> ==1).
9	Reserved.
8	<b>MceRedirSts: machine check exception redirection status.</b> Read-only. This bit is associated with the SMI source specified in <a href="#">MSRC001_0022[RedirSmiEn]</a> .
7:4	Reserved.
3:0	<b>IoTrapSts: IO trap status.</b> Read-only. Each of these bits is associated with each of the respective SMI sources specified in <a href="#">MSRC001_00[53:50] [IO Trap (SMI_ON_IO_TRAP_[3:0])]</a> .

### SMMFEC8 SMM IO Restart Byte

00h on entry into SMM.

If the core entered SMM on an IO instruction boundary, the SMI handler may write this to FFh. This causes the core to re-execute the trapped IO instruction immediately after resuming from SMM. The SMI handler should only write to this byte if [SMMFEC0](#) field V==1; otherwise, the behavior is undefined.

If a second SMI is asserted while a valid IO instruction is trapped by the first SMI handler, the core services the second SMI prior to re-executing the trapped IO instruction. **SMMFEC0** field V==0 during the second entry into SMM, and the second SMI handler must not rewrite this byte.

If there is a simultaneous SMI IO instruction trap and debug breakpoint trap, the processor first responds to the SMI and postpones recognizing the debug exception until after resuming from SMM. If debug registers other than DR6 and DR7 are used while in SMM, they must be saved and restored by the SMI handler. If **SMMFEC8 [SMM IO Restart Byte]**, is set to FFh when the RSM instruction is executed, the debug trap does not occur until after the IO instruction is re-executed.

Bits	Description
7:0	<b>RST: SMM IO Restart Byte.</b> Read-write.

### SMMFEC9 Auto Halt Restart Offset

Bits	Description
7:1	Reserved.
0	<b>HLT: halt restart.</b> Read-write. Upon SMM entry, this bit indicates whether SMM was entered from the Halt state. 0=Entered SMM on a normal x86 instruction boundary. 1=Entered SMM from the Halt state. Before returning from SMM, this bit can be written by the SMI handler to specify whether the return from SMM should take the processor back to the Halt state or to the instruction-execution state specified by the SMM state save area (normally, the instruction after the halt). 0=Return to the instruction specified in the SMM save state. 1=Return to the halt state. If the return from SMM takes the processor back to the Halt state, the HLT instruction is not refetched and re-executed. However, the Halt special bus cycle is broadcast and the processor enters the Halt state.

### SMMFECA NMI Mask

Bits	Description
7:1	Reserved.
0	<b>NmiMask.</b> Read-write. Specifies whether NMI was masked upon entry to SMM. 0=NMI not masked. 1=NMI masked.

### SMMFED8 SMM SVM State

Read-only. This offset stores the SVM state of the processor upon entry into SMM.

Bits	Description
63:4	Reserved.

### SMMFEFC SMM-Revision Identifier

SMM entry state: 0003\_0064h

Bits	Description
31:18	Reserved.
17	<b>BRL.</b> Read-only. Base relocation supported.
16	<b>IOTrap.</b> Read-only. IO trap supported.
15:0	<b>Revision.</b> Read-only.

### SMMFF00 SMM Base Address (SMM\_BASE)

Bits	Description
31:0	See: <a href="#">MSRC001_0111</a> [SmmBase].

#### 2.4.9.2.6 Exceptions and Interrupts in SMM

When SMM is entered, the core masks INTR, NMI, SMI, INIT, and A20M interrupts. The core clears the IF flag to disable INTR interrupts. To enable INTR interrupts within SMM, the SMM handler must set the IF flag to 1. A20M is disabled so that address bit 20 is never masked when in SMM.

Generating an INTR interrupt can be used for unmasking NMI interrupts in SMM. The core recognizes the assertion of NMI within SMM immediately after the completion of an IRET instruction. Once NMI is recognized within SMM, NMI recognition remains enabled until SMM is exited, at which point NMI masking is restored to the state it was in before entering SMM.

While in SMM, the core responds to the DBREQ and STPCLK interrupts, as well as to all exceptions that may be caused by the SMI handler.

#### 2.4.9.2.7 The Protected ASeg and TSeg Areas

These ranges are controlled by [MSRC001\\_0112](#) and [MSRC001\\_0113](#); see those registers for details.

#### 2.4.9.2.8 SMM Special Cycles

Special cycles can be initiated on entry and exit from SMM to acknowledge to the system that these transitions are occurring. These are controlled by [MSRC001\\_0015](#)[RsmSpCycDis, SmiSpCycDis].

### 2.4.9.2.9 Locking SMM

The SMM registers ([MSRC001\\_0112](#) and [MSRC001\\_0113](#)) can be locked from being altered by setting [MSRC001\\_0015](#)[SmmLock]. SBIOS must lock the SMM registers after initialization to prevent unexpected changes to these registers.

### 2.4.9.2.10 Synchronizing SMM Entry (Spring-Boarding)

The BIOS must take special care to ensure that all cores have entered SMM prior to accessing shared IO resources and all core SMI interrupt status bits are synchronized. This generally requires that BIOS waits for all cores to enter SMM.

The following conditions can cause one or more cores to enter SMM without all cores entering SMM:

- More than one IO device in the system is enabled to signal an SMI without hardware synchronization (e.g. using an end of SMI gate).
- A single device may signal multiple SMI messages without hardware synchronization (e.g. using an end of SMI gate).
- An SMI is received while one or more AP cores are in the INIT state. This may occur either during BIOS or secure boot.
- A hardware error prevents a core from entering SMM.

The act of synchronizing cores into SMM is called spring-boarding. Because not all of the above conditions can be avoided, it is recommended that all systems support spring-boarding.

An ACPI-compliant IO hub is required for spring-boarding. Depending on the IO hub design, BIOS may have to set additional end-of-SMI bits to trigger an SMI from within SMM.

The software requirements for the suggested spring-boarding implementation are listed as follows.

- A binary semaphore located in SMRAM, accessible by all cores. For the purpose of this discussion, the semaphore is called CheckSpringBoard. CheckSpringBoard is initialized to zero.
- Two semaphores located in SMRAM, accessible by all cores. For the purpose of this discussion, the semaphores are called NotInSMM and WaitInSMM. NotInSMM and WaitInSMM are initialized to a value equal to the number of cores in the system (NumCPUs).

The following BIOS algorithm describes spring-boarding and is optimized to reduce unnecessary SMI activity. This algorithm must be made part of the SMM instruction sequence for each core in the system.

1. Attempt to obtain ownership of the CheckSpringBoard semaphore with a read-modify-write instruction. If ownership was obtained then do the following, else proceed to step 2:
    - Check all enabled SMI status bits in the IO hub.  
Let Status=enable1&status1 | enable2&status2 | enable3&status3 ... enable n & status n.
    - If (Status==0) then perform the following sub-actions.
      - Trigger an SMI broadcast assertion from the IO hub by writing to the software SMI command port.
      - Resume from SMM with the RSM instruction.
- //Example:
- ```
InLineASM{
    BTS CheckSpringBoard,0; Try to obtain ownership of semaphore
    JC Step_2:
    CALL CheckIOHUB_SMIEVT; proc returns ZF=1 for no events
    JNZ Step_2:
    CALL Do_SpringBoard;Trigger SMI and then RSM
```

```

    Step_2:
}

```

2. Decrement the NotInSMM variable. Wait for (NotInSMM==0). See Note 1.
3. Execute the core-local event SMI handler. Using a third semaphore (not described here), synchronize core execution at the end of the task. After all cores have executed, proceed to step 4. The following is a brief description of the task for each core:
  - Check all enabled core-local SMI status bits in the core's private or MSR address space. Handle the event if possible, or pass information necessary to handle the event to a mailbox for the BSC to handle.
  - An exclusive mailbox must exist for each core for each core local event.
  - Wait for all cores to complete this task at least once.
4. If the current core executing instructions is not the BSC then jump to step 5. If the core executing instructions is the BSC then jump to the modified main SMI handler task, described below.
  - Check all enabled SMI status bits in the IO hub. Check mailboxes for event status.
  - For each event, handle the event and clear the corresponding status bit.
  - Repeat until all enabled SMI status bits are clear and no mailbox events remain.
  - Set NotInSMM=NumCPUs. (Jump to step 5.)
5. Decrement the WaitInSMM variable. Wait for WaitInSMM=0. See Note 2.
6. Increment the WaitInSMM variable. Wait for WaitInSMM=NumCPUs.
7. If the current processor core executing instructions is the BSC then reset CheckSpringBoard to zero.
8. Resume from SMM with the RSM instruction.

#### Notes:

1. To support a secure startup by the secure loader the BIOS must provide a timeout escape from the otherwise endless loop. The timeout value should be large enough to account for the latency of all cores entering SMM. The maximum SMM entrance latency is defined by the platform's IO sub-system, not the processor. A value of twice the watchdog timer count is recommended. See [D18F3x44 \[MCA NB Configuration\]](#) for more information on the watchdog time-out value. If a time-out occurs in the wait loop, the BIOS (the last core to decrement NotInSMM) should record the number of cores that have not entered SMM and all cores must fall out of the loop.
2. If a time-out occurs in the wait loop in step 2, the BIOS must not wait for WaitInSMM=0. Instead it must wait for WaitInSMM=(the number of cores recorded in step 2).
3. If BIOS places APs in the INIT state during any part of the boot process when SMIs may be generated, or may generate SMIs before taking all APs out of their initial microcode reset loop (i.e., before [D18F0x1DC\[CpuEn\]](#) is set), then it is recommended that BIOS keep a record of how many APs are in these two states and exclude these cores from the wait loops. SMIs are not recognized by a processor in these states. AMD does not recommend enabling SMI sources prior to bringing all APs out of these states.

### 2.4.10 Secure Virtual Machine Mode (SVM)

Support for SVM mode is indicated by [CPUID Fn8000\\_0001\\_ECX\[SVM\]](#).

#### 2.4.10.1 BIOS support for SVM Disable

The BIOS should include the following user setup options to enable and disable AMD Virtualization™ technology.

- Enable AMD Virtualization™.
  - [MSRC001\\_0114\[SvmeDisable\]](#) = 0.
  - [MSRC001\\_0114\[Lock\]](#) = 1.
  - [MSRC001\\_0118\[SvmLockKey\]](#) = 0000\_0000\_0000\_0000h.
- Disable AMD Virtualization™.

- [MSRC001\\_0114](#)[SvmeDisable]=1.
- [MSRC001\\_0114](#)[Lock]=1.
- [MSRC001\\_0118](#)[SvmLockKey] = 0000\_0000\_0000\_0000h.

The BIOS may also include the following user setup options to disable AMD Virtualization™ technology.

- Disable AMD Virtualization™, with a user supplied key.
  - [MSRC001\\_0114](#)[SvmeDisable]=1.
  - [MSRC001\\_0114](#)[Lock]=1.
  - [MSRC001\\_0118](#)[SvmLockKey] programmed with value supplied by user. This value should be stored in NVRAM.

## 2.4.11 CPUID Instruction

The CPUID instruction provides data about the features supported by the processor. See [3.18 \[CPUID Instruction Registers\]](#).

### 2.4.11.1 Multi-Core Support

There are two methods for determining multi-core support. A recommended mechanism is provided and a legacy method is also available for existing operating systems. System software should use the correct architectural mechanism to detect the number of physical cores by observing [CPUID Fn8000\\_0008\\_ECX](#)[NC]. The legacy method utilizes the [CPUID Fn0000\\_0001\\_EBX](#)[LogicalProcessorCount].

## 2.5 Power Management

The processor supports many power management features in a variety of systems. [Table 9](#) provides a summary of ACPI states and power management features and indicates whether they are supported.

**Table 9: Power Management Support**

| ACPI/Power Management State              | Supported | Description                                                                                |
|------------------------------------------|-----------|--------------------------------------------------------------------------------------------|
| G0/S0/C0: Working                        | Yes       |                                                                                            |
| G0/S0/C0: Core P-state transitions       | Yes       | <a href="#">2.5.3.1 [Core P-states]</a>                                                    |
| G0/S0/C0: NB P-state transitions         | Yes       | <a href="#">2.5.4.1 [NB P-states]</a>                                                      |
| G0/S0/C0: Hardware thermal control (HTC) | Yes       | <a href="#">2.10.3.1 [PROCHOT_L and Hardware Thermal Control (HTC)]</a>                    |
| G0/S0/Per-core IO-based C-states         | Yes       | <a href="#">2.5.3.2 [Core C-states]</a> and <a href="#">2.5.1.3.2 [Low Power Voltages]</a> |
| G0/S0/C1: Halt                           | Yes       |                                                                                            |
| G0/S0/CC6: Per-compute unit Power gating | Yes       | <a href="#">2.5.3.2 [Core C-states]</a>                                                    |
| G0/S0/CC6: L2 power gating               | Yes       | <a href="#">2.5.3.2 [Core C-states]</a>                                                    |
| G0/S0/PC6: 0V support (VDD power plane). | Yes       | <a href="#">2.5.3.2 [Core C-states]</a> and <a href="#">2.5.1.3.2 [Low Power Voltages]</a> |
| G0/S0/Cx: Cache flushing support         | Yes       | <a href="#">2.5.3.2.3.1 [C-state Probes and Cache Flushing]</a>                            |
| G0/S0: Northbridge C-states              | Yes       | <a href="#">2.5.4.2 [NB C-states]</a>                                                      |
| G1/S1: Stand By (Powered On Suspend)     | No        |                                                                                            |
| G1/S3: Stand By (Suspend to RAM)         | Yes       | <a href="#">2.5.8.1 [S-states]</a>                                                         |
| G1/S4: Hibernate (Suspend to Disk)       | Yes       |                                                                                            |
| G1/S5: Shut Down (Soft Off)              | Yes       |                                                                                            |
| G3 Mechanical Off                        | Yes       |                                                                                            |
| Parallel VID Interface                   | No        | <a href="#">2.5.1 [Processor Power Planes And Voltage Control]</a>                         |
| Serial VID Interface 1                   | No        |                                                                                            |
| Serial VID Interface 2                   | Yes       |                                                                                            |

### 2.5.1 Processor Power Planes And Voltage Control

Refer to the *Electrical Data Sheet* for power plane definitions. See [1.2 \[Reference Documents\]](#).

#### 2.5.1.1 Serial VID Interface

The processor includes an interface to control external voltage regulators, called the serial VID interface (SVI). Only SVI2 is supported. The frequency of SVC for SVI2 is controlled by [D18F3xA0\[Svi2HighFreqSel\]](#). See the *AMD Serial VID Interface 2.0 (SVI2) Specification* for additional details.

##### 2.5.1.1.1 SVI2 Features

The processor supports the following SVI2 features:

- Voltage offsets:
  - VDD: [D18F5x12C](#)[CoreOffsetTrim].
  - VDDNB: [D18F5x188](#)[NbOffsetTrim].
- Load line trim:
  - VDD: [D18F5x12C](#)[CoreLoadLineTrim].
  - VDDNB: [D18F5x188](#)[NbLoadLineTrim].

### 2.5.1.2 Internal VID Registers and Encodings

All VID register fields within the processor are 8-bits wide. The VID encodings to voltage translation for all VID codes are defined by the SVI mode. See the *AMD Serial VID Interface 2.0 (SVI2) Specification* for additional details.

The boot VID is 1.0 volts.

#### 2.5.1.2.1 MinVid and MaxVid Check

Hardware limits the minimum and maximum VID code that is sent to the voltage regulator. The allowed limits are specified in [D18F5x17C](#)[MinVid, MaxVid]. Prior to generating VID-change commands to SVI, the processor filters the InputVid value to the OutputVid as follows (higher VID codes correspond to lower voltages and lower VID codes correspond to higher voltages):

- If InputVid < MaxVid, OutputVid=MaxVid.
  - Else if (InputVid > MinVid) & (MinVid!=00h), OutputVid=MinVid.
  - Else OutputVid=InputVid.

This filtering is applied regardless of the source of the VID-change command.

### 2.5.1.3 Low Power Features

#### 2.5.1.3.1 PSIX\_L Bit

The processor can indicate whether or not it's in a low-voltage state via the PSIX\_L bit. This indicator may be used by the voltage regulator to place itself into a more power efficient mode. PSIX\_L is controlled independently for VDD and VDDNB.

- The processor supports the PSIO\_L and the PSII\_L bits in the data fields of the SVI2 command.
  - PSIO\_L: PSIO\_L for VDD and VDDNB is enabled using [D18F3xA0](#)[PsiVidEn] and [D18F5x17C](#)[NbPsi0VidEn], respectively. Once enabled, the state of PSIO\_L is controlled by [D18F3xA0](#)[PsiVid[7:0]] and [D18F5x17C](#)[NbPsi0Vid]. Changes to the state of PSIO\_L can only occur on VID changes.
  - PSII\_L: The PSII\_L bit for VDD and VDDNB is specified by [D18F5x12C](#)[CorePsi1En] and [D0F0xBC\\_x3F9EC](#)[EnableNbPsi1], respectively. See also [D18F5x188](#)[NbPsi1]. Changes to the state of PSII\_L can occur at any time.

#### 2.5.1.3.1.1 BIOS Requirements for PSIO\_L

Enabling PSIO\_L for the VDD and VDDNB planes depends on support from the voltage regulator and is therefore system specific. The voltage regulator must be able to supply the current required for the processor to operate at the VID code specified in [D18F3xA0](#)[PsiVid[7:0]] and [D18F5x17C](#)[NbPsi0Vid[7:0]]. Depending on the regulator used, AMD recommends one of the following methods:

- PSIO\_L disabled:

- VDD: To set PSI0\_L for the VDD plane, program [D18F3xA0](#)[PsiVidEn]=0.
- VDDNB: To set PSI0\_L for the VDDNB plane, program [D18F5x17C](#)[NbPsi0VidEn]=0.
- PSI0\_L set/clear based on current requirements:
  - VDD: The following algorithm describes how to program PSI0\_L on VDD:

```

PSI_vrm_current = current at which the regulator allows PSI0_L.
previous_voltage = FFh

for (each P-state from P0 to D18F3xDC[HwPstateMaxVal]) {
    pstate_current = ProcIddMax for the current P-state,
                      see 2.5.3.1.7 \[Processor-Systemboard Power Delivery Compatibility Check\];
    pstate_voltage = MSRC001\_00[6B:64][CpuVid] of the current P-state;

    if (current P-state == D18F3xDC[HwPstateMaxVal]) {
        next_pstate_current = 0;
    } else {
        next_pstate_current = ProcIddMax for the next P-state,
                              see 2.5.3.1.7 \[Processor-Systemboard Power Delivery Compatibility Check\];
    }

    if ((pstate_current <= PSI_vrm_current) &&
        (next_pstate_current <= PSI_vrm_current) &&
        (pstate_voltage != previous_voltage)) {
        Program D18F3xA0[PsiVid] = pstate_voltage;
        Program D18F3xA0[PsiVidEn] = 1;
        break;
    }
    previous_voltage = pstate_voltage;
}

```

- VDDNB: The following algorithm describes how to program PSI0\_L on VDDNB:

NbIddMax = [D18F5x16](#)[C:0][NbIddDiv] current.

```

PSI_vrm_current = current at which the VDDNB regulator allows PSI0_L.
previous_voltage = FFh

for (each valid NB P-state starting with NBP0) {
    pstate_current = NbIddMax of the current NB P-state;
    pstate_voltage = D18F5x16[C:0][NbVid] of the current NB P-state;

    if (current P-state is the last valid P-state) {
        next_pstate_current = 0;
    } else {
        next_pstate_current = NbIddMax for the next P-state;
    }

    if ((pstate_current <= PSI_vrm_current) &&
        (next_pstate_current <= PSI_vrm_current) &&
        (pstate_voltage != previous_voltage)) {
        Program D18F5x17C[NbPsi0Vid] = pstate_voltage;
        Program D18F5x17C[NbPsi0VidEn] = 1;
        break;
    }
    previous_voltage = pstate_voltage;
}

```

### 2.5.1.3.2 Low Power Voltages

In order to save power, voltages lower than those normally needed for operation may be applied to the VDD power plane while the processor is in a C-state or S-state. The lower voltage is defined as follows:

- PC6Vid: [D18F5x128](#)[PC6Vid] specifies a voltage that does not retain the CPU caches or the core microarchitectural state. PC6Vid does not allow execution and is only applied to the cores. See [2.5.3.2.3.4 \[Package C6 \(PC6\) State\]](#).

### 2.5.1.4 Voltage Transitions

The processor supports dynamic voltage transitions on the VDD and VDDNB planes. These transitions are requested by either hardware or software during state changes such as reset, P-state changes, and C-state changes. In all cases the VID code passed to the voltage regulator changes from the old value to the new value without stepping through intermediate values. The voltage regulator ramps the voltage directly from the starting voltage to the final voltage, no stepping occurs. See the *AMD Serial VID Interface 2.0 (SVI2) Specification* for additional details.

- If a voltage increase is requested, the processor waits the amount of time specified by [D18F5x12C](#)[WaitVidCompDis] before sending any additional voltage change requests to the voltage regulator or before beginning a frequency transition.
- If a voltage decrease is requested, the processor waits the amount of time specified by [D18F5x128](#)[FastSlamTimeDown] before sending any additional voltage change requests to the voltage regulator. For voltage decreases, the processor does not wait any time before beginning frequency changes.

The processor continues code execution during voltage changes when in the C0 state.

#### 2.5.1.4.1 Hardware-Initiated Voltage Transitions

When software requests any of the following state changes, or hardware determines that any of the following state changes are necessary, hardware coordinates the necessary voltage changes:

- VDD:
  - Core P-state transition. See [2.5.3.1 \[Core P-states\]](#).
  - Package C-state transition. [D18F5x128](#)[PC6Vid] specifies a voltage that does not retain the CPU caches or the core microarchitectural state. PC6Vid does not allow execution and is only applied to the cores. See [2.5.3.2.3.4 \[Package C6 \(PC6\) State\]](#).
  - S-state transition. See [2.5.8.1 \[S-states\]](#).
- VDDNB:
  - NB P-state transition. See [2.5.4.1 \[NB P-states\]](#).
  - S-state transition. See [2.5.8.1 \[S-states\]](#).

#### 2.5.1.4.2 Software-Initiated Voltage Transitions

##### 2.5.1.4.2.1 Software-Initiated NB Voltage Transitions

Software can request voltage changes on the VDDNB power plane using the BIOSMC\_MSG\_VDDNB\_REQUEST software interrupt. To make a voltage change request, software uses the sequence described in [2.13.1 \[Software Interrupts\]](#) with Service Index 3Ah.

Software voltage requests are considered by hardware when taking voltage plane dependencies into account (see [2.5.2.2 \[Dependencies Between Subcomponents on VDDNB\]](#)).

## 2.5.2 Frequency and Voltage Domain Dependencies

### 2.5.2.1 Dependencies Between Cores

Whenever a P-state or C-state is requested on a core (see [2.5.3.1 \[Core P-states\]](#) and [2.5.3.2 \[Core C-states\]](#)), hardware must take the following frequency and voltage domain dependencies into account when deciding whether to make the requested change:

- Cores within a compute unit share a common frequency and voltage domain.
- Compute units within a processor share a common voltage domain, but have independent frequency domains. The voltage is determined by the highest-performance P-state requested on any core.

As a result, the P-state and C-state change requests have the following results:

- If different compute units request different voltages, the VDD voltage is determined by the highest voltage (lowest VID) requested.
- If the cores within a compute unit request different P-states while in C0, frequency and voltage are determined by the highest-performance P-state requested.
- If one core within a compute unit requests a CC6 while the other core is in C0, the frequency and voltage of the compute unit is determined by the core in C0.

### 2.5.2.2 Dependencies Between Subcomponents on VDDNB

Many subcomponents of the processor reside on the VDDNB power plane. Hardware must take voltage domain dependencies into account when determining whether to make a voltage change requested by one of the subcomponents. Whenever a state transition occurs that causes a voltage change request (see [2.5.1.4.1 \[Hardware-Initiated Voltage Transitions\]](#)), or software makes a voltage change request (see [2.5.1.4.2 \[Software-Initiated Voltage Transitions\]](#)), the VDDNB voltage requested by the processor is determined by the highest voltage (lowest VID) request made by any of the subcomponents or by software.

### 2.5.2.3 BIOS Requirements for Power Plane Initialization

- Ensure the following fields are configured to their BIOS recommendations:
  - [D18F3xA0\[Svi2HighFreqSel\]](#).
  - [D18F3xD8\[VSRampSlamTime\]](#).
- Optionally configure [PSIx\\_L](#). Refer to [2.5.1.3.1 \[PSIx\\_L Bit\]](#) for additional details.

## 2.5.3 CPU Power Management

### 2.5.3.1 Core P-states

Core P-states are operational performance states characterized by a unique combination of core frequency and voltage. The processor supports up to 8 core P-states (P0 through P7), specified in [MSRC001\\_00\[6B:64\]](#). Out of cold reset, the voltage and frequency of the compute units is specified by [MSRC001\\_0071\[StartupPstate\]](#).

Support for dynamic core P-state changes is indicated by more than one enabled selection in [MSRC001\\_00\[6B:64\]\[PstateEn\]](#). At least one enabled P-state (P0) is specified for all processors.

Software requests core P-state changes for each core independently using the hardware P-state control mechanism (a.k.a. fire and forget). Support for hardware P-state control is indicated by [CPUID Fn8000\\_0007\\_EDX\[HwPstate\]=1b](#). Software may not request any P-state transitions using the hardware P-state control mechanism until the P-state initialization requirements defined in [2.5.3.1.6 \[BIOS Requirements for Core P-state Initialization and Transitions\]](#) are complete.

The processor supports independently-controllable frequency planes for each compute unit and the NB; and independently-controllable voltage planes. See [2.5.1 \[Processor Power Planes And Voltage Control\]](#) for voltage plane definitions.

The following terms may be applied to each of these planes:

- FID: frequency ID. Specifies the PLL frequency multiplier, relative to the reference clock, for a given domain.
- DID: divisor ID. Specifies the post-PLL power-of-two divisor that can be used to reduce the operating frequency.
- COF: current operating frequency. Specifies the operating frequency as a function of the FID and DID. Refer to [CoreCOF](#) for the CPU COF formula and [NBCOF](#) for the NB COF formula.
- VID: voltage ID. Specifies the voltage level for a given domain. Refer to [2.5.1.2.1 \[MinVid and MaxVid Check\]](#) for encodings.

All FID and DID parameters for software P-states must be programmed to equivalent values for all cores and NBs in the coherent fabric. See [2.5.3.1.1.1 \[Software P-state Numbering\]](#). Refer to [MSRC001\\_00\[6B:64\]](#) and [D18F5x16\[C:0\]](#) for further details on programming requirements.

### 2.5.3.1.1 Core P-state Naming and Numbering

Since the number of boosted P-states may vary from product to product, the mapping between [MSRC001\\_00\[6B:64\]](#) and the indices used to request P-state changes or status also varies. In order to clarify this, two different numbering schemes are used.

#### 2.5.3.1.1.1 Software P-state Numbering

When referring to software P-state numbering, the following naming convention is used:

- Non-boosted P-states are referred to as P0, P1, etc.
  - P0 is the highest power, highest performance, non-boosted P-state.
  - Each ascending P-state number represents a lower-power, lower performance non-boosted P-state than the prior P-state number.
- Boosted P-states are referred to as Pb0, Pb1, etc.
  - Pb0 is the highest-performance, highest-power boosted P-state.
  - Each higher numbered boosted P-state represents a lower-power, lower-performance boosted P-state.

For example, if [D18F4x15C\[NumBoostStates\]](#) contains the values shown below, then the P-states would be named as follows:

**Table 10: Software P-state Naming**

| D18F4x15C[NumBoost-States]=1 |                           | D18F4x15C[NumBoost-States]=3 |                           |
|------------------------------|---------------------------|------------------------------|---------------------------|
| P-state Name                 | Corresponding MSR Address | P-state Name                 | Corresponding MSR Address |
| Pb0                          | MSRC001_0064              | Pb0                          | MSRC001_0064              |
| P0                           | MSRC001_0065              | Pb1                          | MSRC001_0065              |
| P1                           | MSRC001_0066              | Pb2                          | MSRC001_0066              |
| P2                           | MSRC001_0067              | P0                           | MSRC001_0067              |
| P3                           | MSRC001_0068              | P1                           | MSRC001_0068              |
| P4                           | MSRC001_0069              | P2                           | MSRC001_0069              |
| P5                           | MSRC001_006A              | P3                           | MSRC001_006A              |
| P6                           | MSRC001_006B              | P4                           | MSRC001_006B              |

All sections and register definitions use software P-state numbering unless otherwise specified.

#### 2.5.3.1.1.2 Hardware P-state Numbering

When referring to hardware P-state numbering, the following naming convention is used:

- All P-states are referred to as P0, P1, etc.
  - P0 is the highest power, highest-performance P-state, regardless of whether it is a boosted P-state or a non-boosted P-state.
  - Each ascending P-state number represents a lower-power, lower-performance P-state, regardless of whether it is a boosted P-state or not.

#### 2.5.3.1.2 Core P-state Control

Core P-states are dynamically controlled by software and are exposed through ACPI objects (refer to [2.5.3.1.8.3 \[ACPI Processor P-state Objects\]](#)). Software requests a core P-state change by writing a 3 bit index corresponding to the desired P-state number to [MSRC001\\_0062\[PstateCmd\]](#) of the appropriate core. For example, to request P3 for core 0 software would write 011b to core 0's [MSRC001\\_0062\[PstateCmd\]](#).

Boosted P-states may not be directly requested by software. Whenever software requests the P0 state on a processor that supports APM (i.e. writes 000b to [MSRC001\\_0062\[PstateCmd\]](#)), hardware dynamically places the core into the highest-performance P-state possible as determined by APM. See [2.5.9 \[Application Power Management \(APM\)\]](#).

Hardware sequences the frequency and voltage changes necessary to complete a P-state transition as specified by [2.5.3.1.5 \[Core P-state Transition Behavior\]](#) with no additional software interaction required. Hardware also coordinates frequency and voltage changes when differing P-state requests are made on cores that share a frequency or voltage plane. See [2.5.2 \[Frequency and Voltage Domain Dependencies\]](#) for details about hardware coordination.

**Table 11: Software P-state Control**

| D18F4x15C[NumBoostStates]=1 |                                |                           | D18F4x15C[NumBoostStates]=3 |                                |                           |
|-----------------------------|--------------------------------|---------------------------|-----------------------------|--------------------------------|---------------------------|
| P-state Name                | Index Used for Requests/Status | Corresponding MSR Address | P-state Name                | Index Used for Requests/Status | Corresponding MSR Address |
| Pb0                         | n/a                            | MSRC001_0064              | Pb0                         | n/a                            | MSRC001_0064              |
| P0                          | 0                              | MSRC001_0065              | Pb1                         | n/a                            | MSRC001_0065              |
| P1                          | 1                              | MSRC001_0066              | Pb2                         | n/a                            | MSRC001_0066              |
| P2                          | 2                              | MSRC001_0067              | P0                          | 0                              | MSRC001_0067              |
| P3                          | 3                              | MSRC001_0068              | P1                          | 1                              | MSRC001_0068              |
| P4                          | 4                              | MSRC001_0069              | P2                          | 2                              | MSRC001_0069              |
| P5                          | 5                              | MSRC001_006A              | P3                          | 3                              | MSRC001_006A              |
| P6                          | 6                              | MSRC001_006B              | P4                          | 4                              | MSRC001_006B              |

Hardware controls the VID for each voltage domain according to the highest requirement of the frequency domain(s) on each plane. For example, the VID for a 4 compute unit dual-plane system must be maintained at the highest level required for all 4 frequency domains. The number of frequency domains in a voltage domain is package/platform specific. Refer to 2.5.3.1.5 [Core P-state Transition Behavior] for details on hardware P-state voltage control. 2.5.2.3 [BIOS Requirements for Power Plane Initialization] specifies the processor initialization requirements for voltage plane control.

### 2.5.3.1.3 Core P-state Visibility

MSRC001\_0063[CurPstate] reflects the current non-boosted P-state number for each compute unit. For example, if MSRC001\_0063[CurPstate]=010b on compute unit 1, then compute unit 1 is in the P2 state. If a compute unit is in a boosted P-state, MSRC001\_0063[CurPstate] reads back as 0.

The voltage on a compute unit may not correspond to the VID code specified by the current P-state of the compute unit due to voltage plane dependencies. See 2.5.2 [Frequency and Voltage Domain Dependencies]. If a compute unit is in the P0 state (i.e. if MSRC001\_0063[CurPstate]=0), the frequency of the compute unit could be the frequency specified by P0 or any boosted P-state. To determine the frequency of a compute unit, see 2.5.3.3 [Effective Frequency].

### 2.5.3.1.4 Core P-state Limits

Core P-states may be limited to lower-performance values under certain conditions, including:

- HTC. See D18F3x64[HtcPstateLimit].
- Software. See D18F3x68[SwPstateLimit].
- Core Performance Boost. See 2.5.9 [Application Power Management (APM)].
- PROCHOT\_L assertion. See 2.10.3.1 [PROCHOT\_L and Hardware Thermal Control (HTC)].
- SMU. See D18F4x13C[SmuPstateLimit].

P-state limits are applied to all cores on the processor. The current P-state limit is provided in MSRC001\_0061[CurPstateLimit]. Changes to the MSRC001\_0061[CurPstateLimit] can be programmed to trigger interrupts through D18F3x64[PslApicLoEn, PslApicHiEn]. In addition, the maximum P-state value, regardless of the source, is limited as specified in MSRC001\_0061[PstateMaxVal].

### 2.5.3.1.5 Core P-state Transition Behavior

The following rules specify how P-states changes function and interact with other system or processor states:

- If the P-state number is increasing (the compute unit is moving to a lower-performance state), then the COF is changed first, followed by the VID change. If the P-state number is decreasing, then the VID is changed first followed by the COF.
- When the processor initiates a VID change that increases voltage for a voltage domain, no new voltage or frequency changes occur until [D18F3xD8\[VS RampSlamTime\]](#) has expired, regardless of whether any new requests are received. When the processor initiates a VID change that decreases voltage for a voltage domain, new voltage or frequency changes are allowed to occur immediately.
  - This is true regardless of whether the frequency or voltages changes occur as a result of P-state or C-state changes.
- If multiple commands are issued that affect the P-state of a domain prior to when the processor initiates the change of the P-state of that domain, then the processor operates on the last one issued.
- Once a P-state change starts, the P-state state machine (PSSM) continues through completion unless interrupted by a PWROK deassertion. If multiple P-state changes are requested concurrently, the PSSM may group the associated VID changes separately from the associated COF changes.
- Behavior during RESET\_L assertions:
  - All cores are transitioned to C0.
  - VDD VID is transitioned to HWP0 VID. See [MSRC001\\_0064\[CpuVid\]](#).
  - If there is no P-state transition activity, then the compute units and NB remain in the current P-state.
  - If a RESET\_L assertion interrupts a P-state transition, then the COF remains in it's current state at the time RESET\_L is asserted (either the value of the old or the new P-state). BIOS is required to transition to valid COF and VID settings after a warm reset according to the sequence defined in [2.5.3.1.8 \[BIOS COF and VID Requirements After Warm Reset\]](#).
  - After a warm reset [MSRC001\\_0063 \[P-state Status\]](#) is consistent with [MSRC001\\_0071\[CurPstate\]](#). [MSRC001\\_0062 \[P-state Control\]](#) may not be consistent with [MSRC001\\_0071\[CurPstate\]](#).
- The OS controls the P-state through [MSRC001\\_0062 \[P-state Control\]](#), independent of P-state limits described in [D18F3x64\[HtcPstateLimit\]](#), [D18F3x68\[SwPstateLimit\]](#). P-state limits interact with OS-directed P-state transitions as follows:
  - Of all the active P-state limits, the one that represents the lowest-performance P-state number, at any given time, is treated as an upper limit on performance.
  - As the limit becomes active or inactive, or if it changes, the P-state for each compute unit is placed in either the last OS-requested P-state or the new limit P-state, whichever is a lower performance P-state number.
    - If the resulting P-state number exceeds [MSRC001\\_0061\[PstateMaxVal\]](#), regardless of whether it is a limit or OS-requested, then the PstateMaxVal is used instead.

### 2.5.3.1.6 BIOS Requirements for Core P-state Initialization and Transitions

1. Check that [CPUID Fn8000\\_0007\\_EDX\[HwPstate\]](#)=1. If not, P-states are not supported, no P-state related ACPI objects should be generated, and BIOS must skip the rest of these steps.
2. Complete the [2.5.2.3 \[BIOS Requirements for Power Plane Initialization\]](#).
3. Ensure the following fields are configured to their BIOS recommendations:
  - [D18F3xA0\[PIILockTime\]](#).
  - [D18F3xD4\[PowerStepUp, PowerStepDown\]](#).
4. Transition all cores to the minimum performance P-state using the algorithm detailed in [2.5.3.1.8.2 \[Core Minimum P-state Transition Sequence After Warm Reset\]](#).
5. Complete the [2.5.4.1.3.1 \[NB P-state COF and VID Synchronization After Warm Reset\]](#). All cores on a processor must be in the minimum performance P-state prior to executing this sequence.

6. Complete the [2.5.3.1.7 \[Processor-Systemboard Power Delivery Compatibility Check\]](#).
7. Perform the following steps in any order:
  - A. Enable [2.5.9 \[Application Power Management \(APM\)\]](#) as follows:
    - Ensure the following fields are configured to their BIOS recommendations:
      - [D18F4x110\[CSampleTimer\]](#).
      - [D18F4x15C\[ApmMasterEn\]](#).
      - [D18F5xE0\[RunAvgRange\]](#).
    - See your AMD representative for details on how to enable the GPU aspects of [2.5.9 \[Application Power Management \(APM\)\]](#).
    - If [D18F4x15C\[NumBoostStates\] != 0](#), program [D18F4x15C\[BoostSrc\] = 1](#).
  - B. Transition all cores to the maximum performance P-state by writing 0 to [MSRC001\\_0062\[PstateCmd\]](#).
  - C. Create ACPI objects if necessary:
    - Determine the valid set of P-states as indicated by [MSRC001\\_00\[6B:64\]\[PstateEn\]](#).
    - If P-states are not supported, as indicated by only one enabled selection in [MSRC001\\_00\[6B:64\]\[PstateEn\]](#), then BIOS must not generate ACPI-defined P-state objects described in [2.5.3.1.8.3 \[ACPI Processor P-state Objects\]](#). Otherwise, the ACPI objects should be generated to enable P-state support.
  - D. Configure the COF and VID for each processor appropriately based on the sequence described in [2.5.4.1.3 \[BIOS NB P-state Configuration\]](#).
8. Configure [PSIx\\_L](#). Refer to [2.5.1.3.1 \[PSIx\\_L Bit\]](#) for additional details.

### 2.5.3.1.7 Processor-Systemboard Power Delivery Compatibility Check

BIOS must disable processor P-states that require higher power delivery than the systemboard can support. This power delivery compatibility check is designed to prevent system failures caused by exceeding the power delivery capability of the systemboard for the power plane(s) that contain the core(s). Refer to [2.5.1 \[Processor Power Planes And Voltage Control\]](#) for power plane definitions and configuration information. BIOS can optionally notify the user if P-states are detected that exceed the systemboard power delivery capability. Modifications to [MSRC001\\_00\[6B:64\]\[P-state \[7:0\]\]](#) must be applied equally to all cores on the same node. This check does not ensure functionality for all package/socket compatible processor/systemboard combinations.

[MSRC001\\_00\[6B:64\]\[PstateEn\]](#) must be set to 0 for any P-state MSR where [PstateEn=1](#) and the processor current requirement ([ProcIddMax](#)), defined by the following equation, is greater than the systemboard current delivery capability.

$$\text{ProcIddMax} = \text{MSRC001\_00[6B:64][IddValue]} \text{ current} * 1/10^{\text{MSRC001\_00[6B:64][IddDiv]}} * (\text{D18F5x84[CmpCap]}+1)$$

The power delivery check should be applied starting with hardware P0 and continue with increasing P-state indexes (1, 2, 3, and 4) for all enabled P-states. Once a compatible P-state is found using the [ProcIddMax](#) equation the check is complete. All processor P-states with higher indexes are defined to be lower power and performance, and are therefore compatible with the systemboard.

Example:

- [MSRC001\\_0065\[IddValue\]](#) = 32d
- [MSRC001\\_0065\[IddDiv\]](#) = 0d
- [D18F5x84\[CmpCap\]](#) = 1d
- [ProcIddMax](#) = 32 \* 1 \* 2 = 64A per plane

The systemboard must be able to supply  $\geq 64\text{A}$  for the unified core power plane in order to support P1 for this

processor. If the systemboard current delivery capability is < 64A per plane then BIOS must set `MSRC001_0065[PstateEn]=0` for all cores on this node, and continue by checking P2 in the same fashion.

If no P-states are disabled while performing the power delivery compatibility check then BIOS does not need to take any action.

If at least one P-state is disabled by performing the power delivery compatibility check and at least one P-state remains enabled, then BIOS must perform the following steps:

1. If the P-state pointed to by `MSRC001_0063[CurPstate]` is disabled by the power delivery compatibility check, then BIOS must request a transition to an enabled P-state using `MSRC001_0062[PstateCmd]` and wait for `MSRC001_0063[CurPstate]` to reflect the new value.
2. Copy the contents of the enabled P-state MSR (`MSRC001_00[6B:64]`) to the highest performance P-state locations. E.g. if P0 and P1 are disabled by the power delivery compatibility check and P2 - P4 remain enabled, then the contents of P2 - P4 should be copied to P0 - P2 and P3 and P4 should be disabled (`PstateEn=0`). This step uses software P-state numbering. See 2.5.3.1.1.1 [Software P-state Numbering].
3. Request a P-state transition to the P-state MSR containing the COF/VID values currently applied. E.g. If `MSRC001_0063[CurPstate]=100b` and P4 P-state MSR information is copied to P2 in step 2, then BIOS should write 010b to `MSRC001_0062[PstateCmd]` and wait for `MSRC001_0063[CurPstate]` to reflect the new value.
4. If a subset of boosted P-states are disabled, then copy the contents of the P-state MSR pointed to by the highest performance boosted P-state that is enabled to the P-state MSRs pointed to by the boosted P-states that are disabled.
5. If all boosted P-states are disabled, then program `D18F4x15C[BoostSrc]=0`.
6. Adjust the following P-state parameters affected by the P-state MSR copy by subtracting the number of software P-states that are disabled by the power delivery compatibility check. This calculation should not wrap, but saturate at 0. E.g. if P0 and P1 are disabled, then each of the following register fields should have 2 subtracted from them:
  - `D18F3x64[HtcPstateLimit]`
  - `D18F3x68[SwPstateLimit]`
  - `D18F3xDC[HwPstateMaxVal]`

If any node has all P-states disabled after performing the power delivery compatibility check, then BIOS must perform the following steps. This does not ensure operation and BIOS should notify the user of the incompatibility between the processor and systemboard if possible.

1. If `MSRC001_0063[CurPstate] != MSRC001_0061[PstateMaxVal]`, then write `MSRC001_0061[PstateMaxVal]` to `MSRC001_0062[PstateCmd]` and wait for `MSRC001_0063[CurPstate]` to reflect the new value.
2. If `MSRC001_0061[PstateMaxVal] != 000b` copy the contents of the P-state MSR pointed to by `MSRC001_0061[PstateMaxVal]` to `MSRC001_0064` and set `MSRC001_0064[PstateEn]`; Write 000b to `MSRC001_0062[PstateCmd]` and wait for `MSRC001_0063[CurPstate]` to reflect the new value. This step uses software P-state numbering. See 2.5.3.1.1.1 [Software P-state Numbering].
3. Adjust the following fields to 000b.
  - `D18F3x64[HtcPstateLimit]`
  - `D18F3x68[SwPstateLimit]`
  - `D18F3xDC[HwPstateMaxVal]`
4. Program `D18F4x15C[BoostSrc]=0`.

### 2.5.3.1.8 BIOS COF and VID Requirements After Warm Reset

Warm reset is asynchronous and can interrupt P-state transitions leaving the processor in a VID state that does not correspond to `MSRC001_0063[CurPstate]` on any core. The processor frequency after warm reset

corresponds to [MSRC001\\_0063\[CurPstate\]](#). See [2.5.3.1.5 \[Core P-state Transition Behavior\]](#) for P-state transition behavior when RESET\_L is asserted. BIOS is required to transition the processor to valid COF and VID settings corresponding to an enabled P-state following warm reset. The cores may be transitioned to either the maximum or minimum P-state COF and VID settings using the sequences defined in [2.5.3.1.8.1 \[Core Maximum P-state Transition Sequence After Warm Reset\]](#) and [2.5.3.1.8.2 \[Core Minimum P-state Transition Sequence After Warm Reset\]](#). Transitioning to the minimum P-state after warm reset is recommended to prevent undesired system behavior if a warm reset occurs before the [2.5.3.1.7 \[Processor-Systemboard Power Delivery Compatibility Check\]](#) is complete. BIOS is not required to manipulate NB COF and VID settings following warm reset if the warm reset was issued by BIOS to update [D18F5x16\[C:0\]\[NbFid\[5:0\]\]](#).

#### 2.5.3.1.8.1 Core Maximum P-state Transition Sequence After Warm Reset

1. If [MSRC001\\_0071\[CurPstate\]](#) = [D18F3xDC\[HwPstateMaxVal\]](#), then skip step 3 for that core.
2. Write [MSRC001\\_0061\[PstateMaxVal\]](#) to [MSRC001\\_0062\[PstateCmd\]](#) on all cores in the processor.
3. Wait for [MSRC001\\_0071\[CurCpuFid, CurCpuDid\]](#) = [CpuFid[5:0], CpuDid] from [MSRC001\\_00\[6B:64\]](#) indexed by [D18F3xDC\[HwPstateMaxVal\]](#).
4. Wait for [MSRC001\\_0071\[CurCpuVid\]](#) = [CurCpuVid] from [MSRC001\\_00\[6B:64\]](#) indexed by [D18F3xDC\[HwPstateMaxVal\]](#).
5. All previous steps must be completed on all cores prior to continuing the sequence since a compute unit transitions to the highest performance P-state requested on either core.
6. Write 0 to [MSRC001\\_0062\[PstateCmd\]](#) on all cores in the processor.
7. Wait for [MSRC001\\_0071\[CurCpuFid, CurCpuDid\]](#) = [CpuFid[5:0], CpuDid] from [MSRC001\\_00\[6B:64\]](#) indexed by [MSRC001\\_0071\[CurPstateLimit\]](#).
8. If [MSRC001\\_0071\[CurPstateLimit\]](#) != [D18F3xDC\[HwPstateMaxVal\]](#), wait for [MSRC001\\_0071\[CurCpuVid\]](#) = [CpuVid] from [MSRC001\\_00\[6B:64\]](#) indexed by [MSRC001\\_0071\[CurPstateLimit\]](#).
9. Wait for [MSRC001\\_0063\[CurPstate\]](#) = [MSRC001\\_0061\[CurPstateLimit\]](#).

#### 2.5.3.1.8.2 Core Minimum P-state Transition Sequence After Warm Reset

1. If [MSRC001\\_0071\[CurPstate\]](#) = [MSRC001\\_0071\[CurPstateLimit\]](#), then skip step 3 for that core.
2. Write 0 to [MSRC001\\_0062\[PstateCmd\]](#) on all cores in the processor.
3. Wait for [MSRC001\\_0071\[CurCpuFid, CurCpuDid\]](#) = [CpuFid[5:0], CpuDid] from [MSRC001\\_00\[6B:64\]](#) indexed by [MSRC001\\_0071\[CurPstateLimit\]](#).
4. Write [MSRC001\\_0061\[PstateMaxVal\]](#) to [MSRC001\\_0062\[PstateCmd\]](#) on all cores in the processor.
5. Wait for [MSRC001\\_0071\[CurCpuFid, CurCpuDid\]](#) = [CpuFid[5:0], CpuDid] from [MSRC001\\_00\[6B:64\]](#) indexed by [D18F3xDC\[HwPstateMaxVal\]](#).
6. If [MSRC001\\_0071\[CurPstateLimit\]](#) != [MSRC001\\_0071\[CurPstate\]](#), wait for [MSRC001\\_0071\[CurCpuVid\]](#) = [CpuVid] from [MSRC001\\_00\[6B:64\]](#) indexed by [D18F3xDC\[HwPstateMaxVal\]](#).
7. Wait for [MSRC001\\_0063\[CurPstate\]](#) = [MSRC001\\_0062\[PstateCmd\]](#).

#### 2.5.3.1.8.3 ACPI Processor P-state Objects

Processor performance control is implemented through the \_PCT, \_PSS and \_PSD objects in ACPI 2.0 and later revisions. The presence of these objects indicates to the OS that the platform and processor are capable of supporting multiple performance states. Processor performance states are not supported with ACPI 1.0b. BIOS must provide the \_PCT, \_PSS, and \_PSD objects, and define other ACPI parameters to support operating systems that provide native support for processor P-state transitions.

The following rules apply to BIOS generated ACPI objects in multi-core systems. Refer to the appropriate

ACPI specification for additional details:

- All cores must expose the same number of performance states to the OS.
- The respective performance states displayed to the OS for each core must have identical performance and power-consumption parameters (e.g. P0 on core 0 must have the same performance and power-consumptions parameters as P0 on core 1, P1 on core 0 must have the same parameters as P1 on core 1, however P0 can be different than P1).
- Performance state objects must be present under each processor object in the system.

#### 2.5.3.1.8.3.1 **\_PCT (Performance Control)**

BIOS must declare the performance control object parameters as functional fixed hardware. This definition indicates the processor driver understands the architectural definition of the P-state interface associated with [CPUID Fn8000\\_0007\\_EDX\[HwPstate\]=1](#).

- Perf\_Ctrl\_Register = Functional Fixed Hardware
- Perf\_Status\_Register = Functional Fixed Hardware

#### 2.5.3.1.8.3.2 **\_PSS (Performance Supported States)**

A unique **\_PSS** entry is created for each non-boosted P-state. The value contained in the **\_PSS Control** field is written to [MSRC001\\_0062 \[P-state Control\]](#) to request a P-state change to the CoreFreq of the associated **\_PSS** object. The value contained in [MSRC001\\_0063 \[P-state Status\]](#) can be used to identify the **\_PSS** object of the current P-state request by equating [MSRC001\\_0063\[CurPstate\]](#) to the value of the Status field. See [2.5.3.1 \[Core P-states\]](#).

BIOS loops through each of [MSRC001\\_00\[6B:64\]](#) applying the following formulas to create the fields for the **\_PSS** object for for each valid P-state (see [MSRC001\\_00\[6B:64\]\[PstateEn\]](#)). BIOS skips over any P-state MSRs that specify boost P-states (see [D18F4x15C\[NumBoostStates\]](#)).

- CoreFreq (MHz) = Calculated using the formula for [CoreCOF](#).
- Power (mW) = [MSRC001\\_00\[6B:64\]\[CpuVid\]](#) voltage \* [MSRC001\\_00\[6B:64\]\[IddValue\]](#) current \* 1000.
- TransitionLatency (us) and BusMasterLatency (us):
  - If [MSRC001\\_00\[6B:64\]\[CpuFid\[5:0\]\]](#) is the same for all enabled P-states (see [MSRC001\\_00\[6B:64\]\[PstateEn\]](#)) and all boosted P-states:
    - TransitionLatency = BusMasterLatency = (15 steps \* [D18F3xD4\[PowerStepDown\]](#) time \* 1000 us/ns) + (15 steps \* [D18F3xD4\[PowerStepUp\]](#) time \* 1000 us/ns)
  - Else if [MSRC001\\_00\[6B:64\]\[CpuFid\[5:0\]\]](#) is different for any enabled (see [MSRC001\\_00\[6B:64\]\[PstateEn\]](#)) or boost P-states:
    - TransitionLatency = BusMasterLatency = (15 steps \* [D18F3xD4\[PowerStepDown\]](#) time \* 1000 us/ns) + [D18F3xA0\[PllLockTime\]](#) time + (15 steps \* [D18F3xD4\[PowerStepUp\]](#) time \* 1000 us/ns)
  - Example:
    - [MSRC001\\_00\[6B:64\]\[CpuFid\[5:0\]\]](#) is not the same for all P-states
    - [D18F3xD4\[PowerStepDown\]](#) = [D18F3xD4\[PowerStepUp\]](#) = 8h (50 ns/step)
    - [D18F3xA0\[PllLockTime\]](#) = 001b (2 us)
    - TransitionLatency = BusMasterLatency = (15 steps \* 50 ns/step / 1000 us/ns) + 2us + (15 steps \* 50 ns/step / 1000 us/ns) = 3.5 us (round up to 4 us)
- Control/Status:
  - The highest performance non-boosted P-state must have the **\_PSS control** and status fields programmed to 0.
  - Any lower performance non-boosted P-states must have the **\_PSS control** and status fields programmed

in ascending order.

#### 2.5.3.1.8.3.3 **\_PPC (Performance Present Capabilities)**

The **\_PPC** object is optional. Refer to the ACPI specification for details on use and content.

#### 2.5.3.1.8.3.4 **\_PSD (P-state Dependency)**

AMD recommends the ACPI 3.0 **\_PSD** object be generated for each core as follows to cause the cores to transition between P-states independently:

- NumberOfEntries = 5.
- Revision = 0.
- Domain = CPUID Fn0000\_0001\_EBX[LocalApicId[7:2]].
- CoordType = FEh. (HW\_ALL)
- NumProcessors = 2.

A vendor may choose to generate **\_PSD** object to allow cores to transition between P-states together as follows:

- NumberOfEntries = 5.
- Revision = 0.
- Domain = 0.
- CoordType = FCh. (SW\_ALL)
- NumProcessors = CPUID Fn8000\_0008\_ECX[NC] + 1.

BIOS provides an option to choose between either **\_PSD** definition.

#### 2.5.3.1.8.4 **Fixed ACPI Description Table (FADT) Entries**

Declare the following FADT entries:

- PSTATE\_CNT = 00h.
- DUTY\_WIDTH = 00h.

#### 2.5.3.1.8.5 **XPSS (Microsoft® Extended PSS) Object**

Some Microsoft® operating systems require an XPSS object to make P-state changes function properly. A BIOS that implements an XPSS object has special requirements for the **\_PCT** object. See the Microsoft® *Extended PSS ACPI Method Specification* for the detailed requirements to implement these objects.

### 2.5.3.2 **Core C-states**

C-states are processor power states. C0 is the operational state in which instructions are executed. All other C-states are low-power states in which instructions are not executed. When coming out of warm and cold reset, the processor is transitioned to the C0 state.

#### 2.5.3.2.1 **C-state Names and Numbers**

C-states are often referred to by an alphanumeric naming convention, C1, C2, C3, etc. The mapping between ACPI defined C-states and AMD specified C-states is not direct. AMD specified C-states are referred to as IO-based C-states. Up to three IO-based C-states are supported, IO-based C-state 0, 1, and 2. The IO-based C-state index corresponds to the offset added to **MSRC001\_0073**[CstateAddr] to initiate a C-state request. See [2.5.3.2.2 \[C-state Request Interface\]](#). The actions taken by the processor when entering a low-power C-state are configured by software. See [2.5.3.2.3 \[C-state Actions\]](#) for information about AMD specific actions.

### 2.5.3.2.2 C-state Request Interface

C-states are dynamically requested by software and are exposed through ACPI objects (see [2.5.3.2.6 \[ACPI Processor C-state Objects\]](#)). C-states can be requested on a per-core basis. Software requests a C-state change in one of two ways:

- Reading from an IO address: The IO address must be the address specified by [MSRC001\\_0073](#)[CstateAddr] plus an offset of 0 through 7. The processor always returns 0 for this IO read. Offsets 2 through 7 result in an offset of 2.
- Executing the HLT instruction. This is equivalent to reading from the IO address specified by [D18F4x128](#)[HaltCstateIndex].

When software requests a C-state transition, hardware evaluates any frequency and voltage domain dependencies and determines which C-state actions to execute. See [2.5.2 \[Frequency and Voltage Domain Dependencies\]](#) and [2.5.3.2.3 \[C-state Actions\]](#).

### 2.5.3.2.3 C-state Actions

A core takes one of several different possible actions based upon a C-state change request from software. The C-state action fields are defined in [D18F4x11](#)[C:8].

#### 2.5.3.2.3.1 C-state Probes and Cache Flushing

If probes occur after a core enters a non-C0 state, and the caches are not flushed by hardware, the core clock may be ramped back up to the C0 frequency to service the probes, as specified by [D18F4x118/D18F4x11C](#)[CpuPrbEn].

If a core enters a non-C0 state and cache flush is enabled (see [D18F3xDC](#)[CacheFlushOnHaltCtl] and [D18F4x118/D18F4x11C](#)[CacheFlushEn]), a timer counts down for a programmable period of time as specified by [D18F3xDC](#)[CacheFlushOnHaltTmr] or [D18F4x118/D18F4x11C](#)[CacheFlushTmrSel]. When the timer expires, the core flushes its L1 and L2 caches to DRAM and the core clocks are ramped down to a divisor specified by [D18F3xDC](#)[CacheFlushOnHaltCtl]. The timer is reset if the core exits the C-state for any reason. See [2.5.3.2.4.2 \[Cache Flush On Halt Saturation Counter\]](#).

Once a core flushes its caches, probes are no longer sent to that core. This improves probing performance for cores that are in C0.

#### 2.5.3.2.3.2 Core C1 (CC1) State

When a core enters the CC1 state, its clock ramps down to the frequency specified by [D18F4x118/D18F4x11C](#)[ClkDivisorCstAct].

#### 2.5.3.2.3.3 Core C6 (CC6) State

A core can gate off power to its internal logic when it enters any non-C0 state. This power gated state is known as CC6. In order to enter CC6, hardware first enters CC1 and then flushes the caches (see [2.5.3.2.3.1 \[C-state Probes and Cache Flushing\]](#)) before checking [D18F4x118/D18F4x11C](#)[PwrGateEnCstAct]. Power gating reduces the amount of power consumed by the core. VDD voltage is not reduced when a core is in CC6. The following sequence occurs when a core enters the CC6 state:

1. If [MSRC001\\_0071](#)[CurPstate] < [D18F3xA8](#)[PopDownPstate], transition the core P-state to [D18F3xA8](#)[PopDownPstate].
2. L1 and L2 caches are flushed to DRAM. See [2.5.3.2.3.1 \[C-state Probes and Cache Flushing\]](#).
3. Internal core state is saved to DRAM.

- Power is removed from the core and the core PLL/voltage regulator is powered down as specified by [D18F5x128\[CC6PwrDwnRegEn\]](#).

All of the following must be true in order for a core to be placed into CC6:

- [D18F4x118/D18F4x11C\[CacheFlushEn\]](#)=1 for the corresponding C-state action field.
- [D18F4x118/D18F4x11C\[CacheFlushTmrSel\]](#) != 11b for the corresponding C-state action field.
- [D18F4x118/D18F4x11C\[PwrGateEnCstAct\]](#)=1 for the corresponding C-state action field.
- [D18F2x118\[CC6SaveEn\]](#)=1.
- [D18F2x118\[LockDramCfg\]](#)=1.
- The CC6 storage area in DRAM is configured. See [2.9.13 \[DRAM CC6/PC6 Storage\]](#).

The events which cause a core to exit the CC6 state are specified in [2.5.3.2.5 \[Exiting C-states\]](#).

If a warm reset occurs while a core is in CC6, all MCA registers in the core shown in [Table 47](#) are cleared to 0. See [2.15.1 \[Machine Check Architecture\]](#).

The time required to enter and exit CC6 is directly proportional to the core P-state frequency. Slower core frequencies require longer entry and exit times. Latency issues may occur with core P-state frequencies less than 800MHz.

#### 2.5.3.2.3.4 Package C6 (PC6) State

When all cores enter a non-C0 state, VDD can be reduced to a non-operational voltage that does not retain core state. This state is known as PC6 and reduces the amount of static and dynamic power consumed by all cores.

The following actions are taken by hardware prior to PC6 entry:

- If [MSRC001\\_0071\[CurPstate\]](#) < [D18F3xA8\[PopDownPstate\]](#), transition the core P-state to [D18F3xA8\[PopDownPstate\]](#).
- For all cores not in CC6, L1 and L2 caches are flushed to DRAM. See [2.5.3.2.3.1 \[C-state Probes and Cache Flushing\]](#).
- For all cores not in CC6, internal core state is saved to DRAM.
- VDD is transitioned to the VID specified by [D18F5x128\[PC6Vid\]](#).
- If the core PLLs are not powered down during CC6 entry (see [2.5.3.2.3.3 \[Core C6 \(CC6\) State\]](#)), then they are powered down as specified by [D18F5x128\[PC6PwrDwnRegEn\]](#).

All of the following must be true on all cores in order for a package to be placed into PC6:

- [D18F4x118/D18F4x11C\[CacheFlushEn\]](#)=1 for the corresponding C-state action field
- [D18F4x118/D18F4x11C\[CacheFlushTmrSel\]](#) != 11b for the corresponding C-state action field.
- [D18F4x118/D18F4x11C\[PwrOffEnCstAct\]](#)=1 for the corresponding C-state action field.
- [D18F2x118\[CC6SaveEn\]](#)=1.
- [D18F2x118\[LockDramCfg\]](#)=1.
- [MSRC001\\_0015\[HltXSpCycEn\]](#)=1.

#### 2.5.3.2.4 C-state Request Monitors

Deeper C-states have higher entry and exit latencies but provide greater power savings than shallower C-states. To help balance the performance and power needs of the system, the processor can limit access to specific C-states in certain scenarios.

##### 2.5.3.2.4.1 FCH Messaging

The FCH can be notified when the processor transitions package C-states. See the following:

- [D18F4x128](#)[CstateMsgDis].
- [D18F5x178](#)[CstateFusionDis].
- [MSRC001\\_0015](#)[HltXSpCycEn].

#### 2.5.3.2.4.2 Cache Flush On Halt Saturation Counter

A cache flush success monitor tracks the success rate of cache flush timer expirations relative to the core exiting a C-state. Based on the success rate, caches may be flushed immediately without waiting for the cache flush timer to expire. See [D18F4x128](#)[CacheFlushSucMonThreshold]. When the core resumes normal execution, the caches refill as normal.

#### 2.5.3.2.5 Exiting C-states

The following events may cause the processor to exit a non-C0 C-state and return to C0:

- INTR
- NMI
- SMI
- INIT
- RESET\_L assertion

If an INTR is received while a core is in a non-C0 C-state, the state of EFLAGS[IF] and the mechanism used to enter the non-C0 C-state determine the actions taken by the processor.

- Entry via HLT, EFLAGS[IF]==0: The interrupt does not wake up the core.
- Entry via HLT, EFLAGS[IF]==1: The interrupt wakes the core and the core begins execution at the interrupt service routine.
- Entry via IO read, EFLAGS[IF]==0: The interrupt wakes the core and the core begins execution at the instruction after the IN instruction that was used to enter the non-C0 C-state.
- Entry via IO read, EFLAGS[IF]==1: The interrupt wakes the core and the core begins execution at the interrupt service routine.

#### 2.5.3.2.6 ACPI Processor C-state Objects

Processor power control is implemented through the `_CST` object in ACPI 2.0 and later revisions. The presence of the `_CST` object indicates to the OS that the platform and processor are capable of supporting multiple power states. BIOS must provide the `_CST` object and define other ACPI parameters to support operating systems that provide native support for processor C-state transitions. See [2.5.3.2.6.1 \[\\_CST\]](#). See [2.5.3.2.6.2 \[\\_CSD\]](#).

The `_CST` object is not supported with ACPI 1.0b. BIOS should provide FADT entries to support operating systems that are not compatible with ACPI 2.0 and later revisions. See [2.5.3.2.6.3 \[\\_CRS\]](#).

##### 2.5.3.2.6.1 `_CST`

The `_CST` object should be generated for each core as follows:

- Count = 1.
- Register = [MSRC001\\_0073](#)[CstateAddr] + 1.
- Type = 2.
- Latency = 400.
- Power = 0.

### 2.5.3.2.6.2     \_CSD

The \_CSD object should be generated for each core as follows:

- NumberOfEntries = 6.
- Revision = 0.
- Domain = [CPUID Fn0000\\_0001\\_EBX](#)[LocalApicId[7:1]].
- CoordType = FEh. (HW\_ALL)
- NumProcessors = 2.
- Index = 0.

### 2.5.3.2.6.3     \_CRS

BIOS must declare in the root host bridge \_CRS object that the IO address range from [MSRC001\\_0073](#)[CstateAddr] to [MSRC001\\_0073](#)[CstateAddr]+7 is consumed by the host bridge.

### 2.5.3.2.6.4     Fixed ACPI Description Table (FADT) Entries

Declare the following FADT entries:

- P\_LVL2\_LAT = 100.
- P\_LVL3\_LAT = 1001.
- FLAGS.PROC\_C1 = 1.
- FLAGS.P\_LVL2\_UP = 1.

Declare the following P\_BLK entries:

- P\_LVL2 = [MSRC001\\_0073](#)[CstateAddr] + 1.
- P\_LVL3 = 0.

BIOS must declare the PSTATE\_CNT entry as 00h.

### 2.5.3.2.7     BIOS Requirements for Initialization

1. Initialize [MSRC001\\_0073](#)[CstateAddr] with an available IO address. See 2.5.3.2.6.3 [\_CRS].
2. Initialize [D18F4x11](#)[C:8].
3. Generate ACPI objects as described in 2.5.3.2.6 [ACPI Processor C-state Objects].

### 2.5.3.3     Effective Frequency

The effective frequency interface allows software to discern the average, or effective, frequency of a given core over a configurable window of time. This provides software a measure of actual performance rather than forcing software to assume the current frequency of the core is the frequency of the last P-state requested. This can be useful when the P-state is limited by:

- HTC
- [D18F3x68](#)[SwPstateLimit]
- SBI
- CPB

The following procedure calculates effective frequency using [MSR0000\\_00E7](#) [Max Performance Frequency Clock Count (MPERF)] and [MSR0000\\_00E8](#) [Actual Performance Frequency Clock Count (APERF)]:

1. At some point in time, write 0 to both MSRs.
2. At some later point in time, read both MSRs.
3. Effective frequency = (value read from [MSR0000\\_00E8](#) / value read from [MSR0000\\_00E7](#)) \* P0 fre-

quency using software P-state numbering.

Additional notes:

- The amount of time that elapses between steps 1 and 2 is determined by software.
- It is software's responsibility to disable interrupts or any other events that may occur in between the write of [MSR0000\\_00E7](#) and the write of [MSR0000\\_00E8](#) in step 1 or between the read of [MSR0000\\_00E7](#) and the read of [MSR0000\\_00E8](#) in step 2.
- The behavior of [MSR0000\\_00E7](#) and [MSR0000\\_00E8](#) may be modified by [MSRC001\\_0015](#)[EffFreqCntMwait].
- The effective frequency interface provides +/- 50MHz accuracy if the following constraints are met:
- Effective frequency is read at most one time per millisecond.
- When reading or writing [MSR0000\\_00E7](#) and [MSR0000\\_00E8](#) software executes only MOV instructions, and no more than 3 MOV instructions, between the two RDMSR or WRMSR instructions.
- [MSR0000\\_00E7](#) and [MSR0000\\_00E8](#) are invalid if an overflow occurs.

## 2.5.4 NB Power Management

### 2.5.4.1 NB P-states

The processor supports up to four NB P-states (NBP0 through NBP3), specified in [D18F5x16\[C:0\]](#). Each NB P-state consists of the following:

- Enable: [D18F5x16\[C:0\]\[NbPstateEn\]](#).
- NCLK frequency: [D18F5x16\[C:0\]\[NbFid\[5:0\], NbDid\]](#).
- VDDNB voltage: [D18F5x16\[C:0\]\[NbVid\]](#).
- Memory P-state: [D18F5x16\[C:0\]\[MemPstate\]](#). See 2.5.7.1 [Memory P-states].

Out of cold reset, the NB P-state is specified by [D18F5x174\[StartupNbPstate\]](#) and [D18F3xA0\[CofVidProg\]](#). The current NB P-state is specified by [D18F5x174\[CurNbFid\[5:0\], CurNbDid, {CurNbVid\[7\], CurNbVid\[6:0\]\]\]](#).

Although four NB P-states are defined, only two NB P-states are used at any given time, specified by [D18F5x170\[NbPstateHi, NbPstateLo\]](#).

#### 2.5.4.1.1 Northbridge Dynamic Power Management (NB DPM)

Northbridge Dynamic Power Management (NB DPM) dynamically changes which two of the four NB P-states are in use based on GPU activity as follows:

- When the GPU is active :
  - The high NB P-state is specified by [D0F0xBC\\_x3F9E8\[DpmXNbPsHi\]](#).
  - The low NB P-state is specified by [D0F0xBC\\_x3F9E8\[DpmXNbPsLo\]](#).
- When the GPU is idle and the timer specified by [D0F0xBC\\_x3F9EC\[Hysteresis\]](#) has expired:
  - The high NB P-state is specified by [D0F0xBC\\_x3F9E8\[Dpm0PgNbPsHi\]](#).
  - The low NB P-state is specified by [D0F0xBC\\_x3F9E8\[Dpm0PgNbPsLo\]](#).

In addition, hardware forces the NB P-state to the active high or low NB P-state based on the GPU activity level.

#### 2.5.4.1.2 NB P-state Transitions

Hardware selects whether to use the high or low NB P-state based on several criteria as follows:

- Core P-state:
  - [MSRC001\\_00\[6B:64\]](#)[NbPstate].
  - [D18F5x170](#)[NbPstateThreshold].
- GPU activity:
  - The GPU driver selects levels of GPU activity that force the NB P-state to either the high or low state or allow either NB P-state.
- Hysteresis timer:
  - [D18F5x170](#)[NbPstateHiRes, NbPstateLoRes].
- The following configuration registers:
  - [D18F5x170](#)[SwNbPstateLoDis, NbPstateDisOnP0].
  - [MSRC001\\_0071](#)[NbPstateDis].

Once the NB determines that an NB P-state transition is necessary, the NB executes the following sequence:

1. If transitioning from the low NB P-state to the high NB P-state, transition VDDNB voltage.
2. If the GPU is enabled as specified by [D18F5x178](#)[SwGfxDis], wait for display buffer to fill.
3. Quiesce all active cores.
4. If the internal GPU is enabled as specified by [D18F5x178](#)[SwGfxDis], wait for display buffer to fill.
5. Stop memory traffic and place DRAM into self-refresh.
6. Transition NCLK frequency.
7. Update NB P-state specific DRAM settings within hardware, see [D18F2x210\\_dct\[3:0\]\\_nbp\[3:0\]](#).
8. Take DRAM out of self-refresh and allow memory traffic.
9. Wake up cores.
10. If transitioning from the high NB P-state to the low NB P-state, transition VDDNB voltage.

### 2.5.4.1.3 BIOS NB P-state Configuration

#### 2.5.4.1.3.1 NB P-state COF and VID Synchronization After Warm Reset

BIOS performs the following sequence on one core. This is done after any warm reset and before [2.9.9 \[DCT/DRAM Initialization and Resume\]](#).

1. Temp1=[D18F5x170](#)[SwNbPstateLoDis].
2. Temp2=[D18F5x170](#)[NbPstateDisOnP0].
3. Temp3=[D18F5x170](#)[NbPstateThreshold].
4. Temp4=[D18F5x170](#)[NbPstateGnbSlowDis].
5. If [MSRC001\\_0070](#)[NbPstate]=0, go to step 6. If [MSRC001\\_0070](#)[NbPstate]=1, go to step 11.
6. Write 1 to [D18F5x170](#)[NbPstateGnbSlowDis].
7. Write 0 to [D18F5x170](#)[SwNbPstateLoDis, NbPstateDisOnP0, NbPstateThreshold].
8. Wait for [D18F5x174](#)[CurNbPstate] = [D18F5x170](#)[NbPstateLo] and [D18F5x174](#)[CurNbFid[5:0], CurNbDid]=[NbFid[5:0], NbDid] from [D18F5x16\[C:0\]](#) indexed by [D18F5x170](#)[NbPstateLo].
9. Set [D18F5x170](#)[SwNbPstateLoDis]=1.
10. Wait for [D18F5x174](#)[CurNbPstate] = [D18F5x170](#)[NbPstateHi] and [D18F5x174](#)[CurNbFid[5:0], CurNbDid]=[NbFid[5:0], NbDid] from [D18F5x16\[C:0\]](#) indexed by [D18F5x170](#)[NbPstateHi]. Go to step 15.
11. Write 1 to [D18F5x170](#)[SwNbPstateLoDis].
12. Wait for [D18F5x174](#)[CurNbPstate] = [D18F5x170](#)[NbPstateHi] and [D18F5x174](#)[CurNbFid[5:0], CurNbDid]=[NbFid[5:0], NbDid] from [D18F5x16\[C:0\]](#) indexed by [D18F5x170](#)[NbPstateHi].
13. Write 0 to [D18F5x170](#)[SwNbPstateLoDis, NbPstateDisOnP0, NbPstateThreshold].
14. Wait for [D18F5x174](#)[CurNbPstate] = [D18F5x170](#)[NbPstateLo] and [D18F5x174](#)[CurNbFid[5:0], CurNbDid]=[NbFid[5:0], NbDid] from [D18F5x16\[C:0\]](#) indexed by [D18F5x170](#)[NbPstateLo].

15. Set [D18F5x170](#)[SwNbPstateLoDis]=Temp1, [D18F5x170](#)[NbPstateDisOnP0]=Temp2, and [D18F5x170](#)[NbPstateThreshold]=Temp3, and [D18F5x170](#)[NbPstateGnbSlowDis]=Temp4.

#### 2.5.4.1.3.2 NB P-state Transitions

During boot when [D18F5x174](#)[NbPstateDis]=0, BIOS forces the processor to the desired NB P-states using the following steps:

1. Save the values in [D18F5x170](#) for later restoration to unforce the NB P-state.
2. Set the desired NB P-state pointers, [D18F5x170](#)[NbPstateHi, NbPstateLo].
3. Transition to the desired state as follows:
  - In order to transition to [D18F5x170](#)[NbPstateHi], program [D18F5x170](#) as follows:
    - SwNbPstateLoDis = 1.
    - Wait for [D18F5x174](#)[CurNbPstate] to equal NbPstateHi.
  - In order to transition to [D18F5x170](#)[NbPstateLo], program [D18F5x170](#) as follows:
    - SwNbPstateLoDis = NbPstateDisOnP0 = NbPstateThreshold = 0.
    - Wait for [D18F5x174](#)[CurNbPstate] to equal NbPstateLo.

BIOS performs the following to release the NB P-state force:

4. Release the NB P-state force by restoring initial [D18F5x170](#) values.
  - Restore the initial [D18F5x170](#)[SwNbPstateLoDis, NbPstateDisOnP0, NbPstateLo] values.
  - Restore the initial [D18F5x170](#)[NbPstateThreshold, NbPstateHi] values.

#### 2.5.4.1.3.3 NB P-state Configuration for Runtime

Please see your AMD representative for details.

#### 2.5.4.2 NB C-states

NB C-states are package-level actions that occur only when all cores enter a non-C0 state (see [2.5.3.2 \[Core C-states\]](#)). The NB C-state actions are:

- DRAM self-refresh (see [2.5.7.2 \[DRAM Self-Refresh\]](#)):
  - Enable bit: [D18F4x118/D18F4x11C](#)[SelfRefr].
  - Entry requirements:
    - No outstanding GPU traffic or traffic from a link.
  - Exit conditions (any of the following must be true):
    - The local APIC timer expires. See [2.4.9.1 \[Local APIC\]](#).
    - New GPU traffic or traffic from a link.
    - A P-state limit update (see [2.5.3.1.4 \[Core P-state Limits\]](#)) causes the most restrictive P-state limit to become a higher number than the current P-state for any core in CC1.
- NB clock gating:
  - Enable bit: [D18F4x118/D18F4x11C](#)[NbClkGate].
  - Entry requirements:
    - No outstanding GPU traffic or traffic from a link.
  - Exit conditions (any of the following must be true):
    - The local APIC timer expires. See [2.4.9.1 \[Local APIC\]](#).
    - New GPU traffic or traffic from a link.
    - A P-state limit update (see [2.5.3.1.4 \[Core P-state Limits\]](#)) causes the most restrictive P-state limit to become a higher number than the current P-state for any core in CC1.

NOTE: For SERVER system solutions, NB power gating should be disabled by setting [D18F4x118/D18F4x11C\[NbPwrGate\]](#) = 0 in the BIOS. BIOS setting of [D18F4x118/D18F4x11C\[NbPwrGate\]](#) = 1 should be set for client systems.

- NB power gating:
  - Enable bit: [D18F4x118/D18F4x11C\[NbPwrGate\]](#).
  - Entry requirements (all of the following must be true):
    - No outstanding GPU traffic or traffic from a link.
    - All cores are in CC6.
    - DRAM is either in or entering self-refresh.
  - Exit conditions (any of the following must be true):
    - The local APIC timer expires. See [2.4.9.1 \[Local APIC\]](#).
    - New GPU traffic or traffic from a link.
    - A P-state limit update (see [2.5.3.1.4 \[Core P-state Limits\]](#)) causes the most restrictive P-state limit to become a higher number than the current P-state for any core in CC1.

When entering NB C-states, the actions are taken in the following order:

1. DRAM self-refresh.
2. NB clock gating.
3. NB power gating.

When exiting NB C-states, the actions are taken in the following order:

1. NB power gating.
2. NB clock gating.
3. DRAM self-refresh.

### 2.5.4.3 Fuse Power Gating

Fuse controller can gate off power to its internal logic when no fuse activity is detected for a period of time. Fuse controller exits power gated state when it detects an event that requires access to the fuses.

### 2.5.5 Bandwidth Requirements

- The frequency relationship of (core COF / NB COF)  $\leq 6$  must be maintained for all supported P-state combinations. E.g., a core P0 COF of 4.0 GHz could not be combined with a NB P0 COF of 0.6 GHz; the NB P0 COF would have to be 0.8 GHz or greater; if the NB P0 COF is 1.2 GHz, then the NB P1 COF of 0.6 GHz may only be supported if the corresponding core P-state specify a COF of 3.0 GHz or less.
- All core P-states are required to be defined such that (NB COF/core COF)  $\leq 32$ , for all NB/core P-state combinations. E.g., if the NB COF is 4.8 GHz then the core COF must be no less than 150 MHz.
- All core P-states must be defined such that [CoreCOF](#)  $\geq 500$  MHz.
- All core P-states must be defined such that [MSRC001\\_00\[6B:64\]\[CpuFid\[5:0\]\]](#)  $\leq 22h$ .
- All NB P-states must be defined such that [D18F5x16\[C:0\]\[NbFid\[5:0\]\]](#)  $\leq 2Eh$ .
- [NBCOF](#)  $\geq$  MEMCLK frequency.
- [NBCOF](#)  $\geq 700$  MHz.
- [NBCOF](#)  $< 2.4$  GHz.

### 2.5.6 GPU and Root Complex Power Management

#### 2.5.6.1 Dynamic Power Management (DPM)

The processor supports dynamic GPU frequency changes along with VDDNB voltage change requests, known

as Dynamic Power Management (DPM). Once initialized, hardware dynamically monitors processor utilization and adjusts the frequencies and voltage based on that utilization. For DPM, higher numbered states represent higher performance and lower numbered states represent lower performance.

#### 2.5.6.1.1 Activity Monitors

The processor contains activity monitors which track the usage level of different processor subcomponents. A binary signal from each subcomponent is used to determine whether that subcomponent is busy. On each clock cycle, the activity monitor samples the signal from each unmasked subcomponent.

See [D0F0xBC\\_xC020\\_0110](#) for LCLK DPM activity monitor.

The output of the activity monitor is then used to determine whether the DPM state should be changed.

#### 2.5.6.1.2 SCLK DPM

SCLK DPM consists of up to 8 states. Any number of states up through 8 may be used and there is no requirement that the states be contiguous.

#### 2.5.6.1.3 LCLK DPM

LCLK DPM consists of up to 8 states. Any number of states up through 8 may be used and there is no requirement that the states be contiguous. Each state is made up of the following parameters.

- Valid bit: [D0F0xBC\\_x3FD\[8C:00:step14\]\[StateValid\]](#).
- Voltage change hysteresis threshold: [D0F0xBC\\_x3FD\[8C:00:step14\]\[LowVoltageReqThreshold\]](#).
- Divisor: [D0F0xBC\\_x3FD\[8C:00:step14\]\[LclkDivider\]](#).
- VID: [D0F0xBC\\_x3FD\[8C:00:step14\]\[VID\]](#).
  - See 2.5.2.2 [Dependencies Between Subcomponents on VDDNB].
- State change hysteresis thresholds: [D0F0xBC\\_x3FD\[94:08:step14\]\[HysteresisUp, HysteresisDown\]](#).
- Activity thresholds: [D0F0xBC\\_x3FD\[9C:10:step14\]\[ActivityThreshold\]](#).
- Residency counter: See [D0F0xBC\\_x3FD\[94:08:step14\]\[ResidencyCounter\]](#).

LCLK DPM is enabled by setting [D0F0xBC\\_x3FDC8\[LclkDpmEn\]](#). LCLK DPM voltage changes are enabled using [D0F0xBC\\_x3FDC8\[VoltageChgEn\]](#). When LCLK DPM is first enabled, the DPM state is transitioned to [D0F0xBC\\_x3FDC8\[LclkDpmBootState\]](#).

#### 2.5.6.2 GPU and Root Complex Power Gating

Several subcomponents of the GPU and root complex can be power gated when not in use.

- **GPU:** GPU power gating is initialized and enabled by software (see [GpuEnabled](#) and [D0F0x7C\[ForceIntGfxDisable\]](#)). Once initialized and enabled, the GPU is power gated by hardware when inactive and is ungated by hardware when needed. When internal GPU is disabled by BIOS, BIOS is responsible for power gating the GPU.
- **UVD:** UVD is power gated by software when not in use and is ungated by software when needed. UVD's internal state is not saved and UVD goes through an internal reset when power is restored.
- **GMC:** GMC power gating is initialized and enabled by software. Once initialized and enabled, GMC is power gated by hardware when inactive and is ungated by hardware when needed. GMC's state is saved internally. If the internal GPU is disabled, either by hardware (fusing) or by software, software is responsible

for power gating GMC.

- **VCE:** VCE is power gated by software when not in use and is ungated by software when needed. VCE's internal state is not saved and VCE goes through an internal reset when power is restored.
- **DCE:** DCE is power gated by software when there is no display connected. DCE's internal state is not saved and DCE goes through an internal reset when power is restored.
- **PCIe:** Any core that does not contain the UMI link can be power gated when it is not in use. In addition, the individual phys on the TX and RX sides of each link can be power gated when the links are not connected. During POST and runtime, several software components inform the SMU whether the link core or the link phys are in use. SMU power gates or ungates the link core and the link phys as needed.

## 2.5.7 DRAM Power Management

### 2.5.7.1 Memory P-states

The processor supports up to 2 memory P-states, M0 and M1. Each memory P-state consists of the following:

- MEMCLK frequency
- A set of frequency dependent DRAM timing and configuration registers

See [2.9 \[DRAM Controllers \(DCTs\)\]](#) for DRAM technology specific information and requirements.

All valid memory P-states are associated with a specific NB P-state, as specified by [D18F5x16\[C:0\]\[MemPstate\]](#). When hardware transitionsto a new NB P-state, the memory P-state is transitioned to that specified by the new NB P-state.

Out of cold reset the current memory P-state is M0. The P-state value specified by [D18F5x16\[C:0\]\[MemPstate\]](#) of the NB P-state indexed by [D18F5x174\[StartupNbPstate\]](#) is invalid. Support for dynamic memory P-state changes is indicated by [D18F3xE8\[MemPstateCap\]=1](#) and one or more [D18F5x16\[C:0\]\[MemPstate\]=1](#); otherwise M0 is used by hardware for configuration purposes.

During boot, and if [D18F5x170\[MemPstateDis\]=0](#), the BIOS can disable memory P-states using the following steps:

1. Program [D18F5x170\[MemPstateDis\]=1](#).
2. Program [D18F5x16\[C:0\]\[MemPstate\]=0](#).

### 2.5.7.2 DRAM Self-Refresh

DRAM is placed into self-refresh on S3 entry (see [2.5.8.1.1 \[ACPI Suspend to RAM State \(S3\)\]](#)).

In addition to S3, DRAM is placed into self-refresh in S0 in the following two scenarios:

- NB P-state transitions (see [2.5.4.1 \[NB P-states\]](#)).
- NB C-states (see [2.5.4.2 \[NB C-states\]](#)).

The following requirements must be met before hardware places DRAM into self-refresh:

- No pending traffic.
- One of the following is true:
  - The GPU is idle and the internal display buffer is full.
  - The internal GPU is disabled.

Once the above requirements are met, hardware places DRAM into self-refresh.

Early self-refresh occurs when DRAMs are placed in self-refresh before expiration of the cache flush timer. See [D18F4x118/D18F4x11C\[SelfRefrEarly\]](#) and [D18F5x128\[SelfRefrEarlyDis\]](#). If early self-refresh is enabled, the DRAMs are taken out of self-refresh to perform the flush operation when the cache flush timer expires and then placed back into self-refresh.

The following are events that cause DRAM to transition out of self-refresh:

- Core transitioning to C0.
- Incoming request from any link or the GMC
- P-state limit update, only in the case when all cores are not in the power gated (CC6) state.

To save additional power, hardware always tristates MEMCLK when entering self-refresh.

### 2.5.7.3 Stutter Mode

DRAM is most commonly placed in self-refresh due to stutter mode when the internal GPU is in use. The display buffer in the GPU is a combination of a large buffer known as the DMIF (Display Memory Interface FIFO) and a smaller line buffer. The DMIF takes data originating from DRAM and sends it to the line buffer to draw to the screen. When the data level in the DMIF is full, DRAM is placed in self-refresh, and incoming DRAM requests are queued. As the DMIF drains, it eventually falls below a predefined watermark level, at which point hardware pulls DRAM out of self-refresh and services all the requests in the queue. Once all the requests are complete and the DMIF is full again, a transition back into self-refresh occurs if the stutter mode conditions are still met.

#### 2.5.7.3.1 System BIOS Requirements for Stutter Mode Operation During POST

BIOS creates a data structure in memory containing information about the processor for use by the driver. Please see your AMD representative for more information.

### 2.5.7.4 EVENT\_L

EVENT\_L is a level sensitive input to the processor. When asserted, the actions specified by [D18F2xA4](#) are taken. EVENT\_L is generally asserted to indicate that a DRAM high temperature condition exists. The minimum assertion time for EVENT\_L is 15 ns. The minimum deassertion time for EVENT\_L is 15 ns.

- EVENT\_L is pulled to VDDIO on the motherboard.
- EVENT\_L is ignored while:
  - PWROK is de-asserted.
  - RESET\_L is asserted.
- BIOS must ensure that throttling is disabled (see [D18F2xA4\[CmdThrottleMode\]](#)) until DRAM training is complete.

See [2.9.14 \[DRAM On DIMM Thermal Management and Power Capping\]](#).

## 2.5.8 System Power Management

### 2.5.8.1 S-states

S-states are ACPI defined sleep states. S0 is the operational state. All other S-states are low-power states in which various voltage rails in the system may or may not be powered. See the ACPI specification for descriptions of each S-state. The only other S-state supported is S5.

### 2.5.8.1.1 ACPI Suspend to RAM State (S3)

The processor supports the ACPI-defined S3 state. Software is responsible for restoring the state of the processor's registers when resuming from S3. All registers in the processor that BIOS initialized during the initial boot must be restored. The method used to restore the registers is system specific.

During S3 entry, software is responsible for transitioning the processor to Memory Pstate0. See [2.5.7.1 \[Memory P-states\]](#).

During S3 entry, system memory enters self-refresh mode (see [2.5.7.2 \[DRAM Self-Refresh\]](#)). Software is responsible for bringing memory out of self-refresh mode when resuming from S3. To bring memory out of self-refresh mode. See [2.9.9 \[DCT/DRAM Initialization and Resume\]](#).

Many of the systemboard power planes for the processor are powered down during S3. Refer to the Electrical Data Sheet for the following:

- Power plane electrical requirements during S3.
- Power plane sequencing requirements on S3 entry and exit.
- System signal states for both inputs (e.g. PWROK and RESET\_L) and outputs (e.g. VID[\*], PSI\_L bit, THERMTRIP\_L, etc.) during S3.
- System signal sequencing requirements on S3 entry and exit.
- System management message sequencing on S3 entry and exit.

## 2.5.9 Application Power Management (APM)

Application Power Management (APM) allows the processor to deterministically provide maximum performance while remaining within the specified power delivery and removal envelope. APM dynamically monitors processor activity and generates an approximation of power consumption. If power consumption exceeds a defined power limit, a P-state limit is applied by APM hardware to reduce power consumption. APM ensures that average power consumption over a thermally significant time period remains at or below the defined power limit. This allows P-states to be defined with higher frequencies and voltages than could be used without APM.

### 2.5.9.1 Core Performance Boost (CPB)

These P-states are referred to as boosted P-states.

- Support for APM is specified by [CPUID Fn8000\\_0007\\_EDX\[CPB\]](#).
- APM is enabled if all of the following conditions are true:
  - [MSRC001\\_0015\[CpbDis\]](#) = 0 for all cores.
  - [D18F4x15C\[ApmMasterEn\]](#) = 1.
  - [D18F4x15C\[BoostSrc\]](#) = 01b.
  - [D18F4x15C\[NumBoostStates\]](#) != 0.
- APM can be dynamically enabled and disabled through [MSRC001\\_0015\[CpbDis\]](#). If core performance boost (CPB) is disabled, a P-state limit is applied. The P-state limit restricts cores to the highest performance non-boosted P-state.
- All P-states, both boosted and non-boosted, are specified in [MSRC001\\_00\[6B:64\]](#).
- The number of boosted P-states is specified by [D18F4x15C\[NumBoostStates\]](#).
  - The number of boosted P-states may vary from product to product.
- Two levels of boosted P-states are supported. Compute units can be placed in the first level of boosted P-states if the processor power consumption remains within the TDP limit. The second level of boosted P-

states is C-state Boost. See [2.5.9.1.1 \[C-state Boost\]](#).

- All boosted P-states are always higher performance than non-boosted P-states.
- To ensure proper operation, boosted P-states should be hidden from the operating system. BIOS should not provide ACPI \_PSS entries for boosted P-states. See [2.5.3.1.8.3.2 \[\\_PSS \(Performance Supported States\)\]](#).
- The lowest-performance P-state CPB limits the processor to is the highest-performance non-boosted P-state.

#### **2.5.9.1.1 C-state Boost**

C-state Boost can only be achieved if a subset of cores/compute units are in CC6 and the processor power consumption remains within the TDP limit. See [D18F4x16C](#)[CstateCnt, CstateBoost, CstateCores].

#### **2.5.9.2 TDP Limiting**

TDP limiting is a mechanism for capping the power consumption of the processor through a TDP limit.

#### **2.5.9.3 Bidirectional Application Power Management (BAPM)**

Bidirectional Application Power Management (BAPM) is an algorithm to enable fine grained power transfers between the core and GPU.

#### **2.5.9.4 Configurable TDP (cTDP)**

Configurable TDP (cTDP) provides flexibility to AMD APU, traditionally defined to be at fixed nominal TDPs, to fit well in platforms that have thermal solutions designed for lower than nominal TDP. For example, a 35W OPN with the cTDP feature will be able to function and perform well in platforms designed for 30W.

## 2.6 Performance Monitoring

The processor includes support for two methods of monitoring processor performance:

- [2.6.1 \[Performance Monitor Counters\]](#).
- [2.6.2 \[Instruction Based Sampling \(IBS\)\]](#).

### 2.6.1 Performance Monitor Counters

The following types of performance counters are supported:

- [2.6.1.1 \[Core Performance Monitor Counters\]](#), consisting of one set located in each core of each compute unit.
- [2.6.1.2 \[NB Performance Monitor Counters\]](#), consisting of one set located in each node.

The accuracy of the performance counters is not ensured. The performance counters are not assured of producing identical measurements each time they are used to measure a particular instruction sequence, and they should not be used to take measurements of very small instruction sequences. The RDPMC instruction is not serializing, and it can be executed out-of-order with respect to other instructions around it. Even when bound by serializing instructions, the system environment at the time the instruction is executed can cause events to be counted before the counter value is loaded into EDX:EAX.

To accurately start counting with the write that enables the counter, disable the counter when changing the event and then enable the counter with a second MSR write.

Writing the performance counters can be useful if there is an intention for software to count a specific number of events, and then trigger an interrupt when that count is reached. An interrupt can be triggered when a performance counter overflows. Software should use the WRMSR instruction to load the count as a two's-complement negative number into the performance counter. This causes the counter to overflow after counting the appropriate number of times.

In addition to the RDMSR instruction, the performance counter registers can be read using a special read performance-monitoring counter instruction, RDPMC.

#### 2.6.1.1 Core Performance Monitor Counters

The core performance monitor counters are used by software to count specific events that occur in a core of the compute unit. Each core of each compute unit provides six 48-bit performance counters. Unless otherwise specified, the events count only the activity of the core, not activity caused by the other core of the compute unit.

[MSRC001\\_020\[A,8,6,4,2,0\]](#) [Performance Event Select (PERF\_CTL[5:0])] specify the events to be monitored and how they are monitored. [MSRC001\\_020\[B,9,7,5,3,1\]](#) [Performance Event Counter (PERF\_CTR[5:0])] are the counters. [MSRC001\\_00\[03:00\]](#) is the legacy alias for [MSRC001\\_020\[6,4,2,0\]](#). [MSRC001\\_00\[07:04\]](#) is the legacy alias for [MSRC001\\_020\[7,5,3,1\]](#). Support for [MSRC001\\_020\[B:0\]](#) is indicated by [CPUID Fn8000\\_0001\\_ECX\[PerfCtrExtCore\]](#).

All of the events are specified in [3.23 \[Core Performance Counter Events\]](#).

Some performance monitor events have a maximum count per clock that exceeds one event per clock. These performance events are called multi-events. Some counters support a greater multi-event count per clock than others. Events that are multi-events will specify the maximum multi-event count per clock. E.g. The number of events logged per cycle can vary from 0 to X. An event that doesn't specify multi-event is implied to be a max-

imum of 1 event per clock. Undefined results will be produced if an multi-event is selected that exceeds that counters capabilities. The following list specifies the maximum number of multi-events supported by each counter:

- PERF\_CTL[0]: 31 multi-event per clock maximum.
- PERF\_CTL[1]: 7 multi-event per clock maximum.
- PERF\_CTL[2]: 7 multi-event per clock maximum.
- PERF\_CTL[3]: 63 multi-event per clock maximum.
- PERF\_CTL[4]: 7 multi-event per clock maximum.
- PERF\_CTL[5]: 7 multi-event per clock maximum.

Not all performance monitor events can be counted on all counters. The performance counter registers are generally assigned to specific blocks of the core according to [Table 12](#); however, there are exceptions when an events is implemented by another block of the core and therefore has the counter restrictions of that block. Each core event description starts with one of the following terms to indicate which counters support that event. Selecting an event for a counter that does not support that counter will produce undefined results.

**Table 12: Core PMC mapping to PERF\_CTL[5:0]**

| Term                 | Definition                                                                                                                         |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>PERF_CTL[5:0]</b> | PERF_CTL[5:0] are used to count events in the LS/DC and EX where the number of events logged per cycle can vary up to 7.           |
| <b>PERF_CTL[3,0]</b> | PERF_CTL[3,0] are used to count events in the LS/DC and EX where the number of events logged per cycle can vary up to 31.          |
| <b>PERF_CTL[0]</b>   | PERF_CTL[0] are used to count events in the LS/DC, EX, IF/DE and CU where the number of events logged per cycle can vary up to 31. |
| <b>PERF_CTL[3]</b>   | PERF_CTL[3] are used to count events in the LS/DC, EX and FP where the number of events logged per cycle can vary up to 63.        |
| <b>PERF_CTL[2:0]</b> | PERF_CTL[2:0] are used to count events in the IF/DE and CU; The number of events logged per cycle can vary up to 7.                |
| <b>PERF_CTL[5:3]</b> | PERF_CTL[5:3] are used to count events in the FP; The number of events logged per cycle can vary up to 7.                          |

### 2.6.1.2 NB Performance Monitor Counters

The NB performance monitor counters are used by software to count specific events that occur in the NB. Each node provides four 48-bit performance counters. Since the northbridge performance counter register are shared by all cores on a node, monitoring of northbridge events should only be performed by one core on a node.

[MSRC001\\_024\[6,4,2,0\]](#) [Northbridge Performance Event Select (NB\_PERF\_CTL[3:0])] and [MSRC001\\_024\[7,5,3,1\]](#) [Northbridge Performance Event Counter (NB\_PERF\_CTR[3:0])] specify the events to be monitored and how they are monitored. Support for [MSRC001\\_024\[7:0\]](#) is indicated by [CUID Fn8000\\_0001\\_ECX\[PerfCtrExtNB\]](#).

All of the events are specified in [3.24 \[NB Performance Counter Events\]](#).

All NB performance monitor events can be counted on all counters.

All NB performance events are one event per clock.

NB performance counters do not support APIC interrupt capability.

## 2.6.2 Instruction Based Sampling (IBS)

IBS is a code profiling mechanism that enables the processor to select a random instruction fetch or micro-op after a programmed time interval has expired and record specific performance information about the operation. An interrupt is generated when the operation is complete as specified by [MSRC001\\_103A \[IBS Control\]](#). An interrupt handler can then read the performance information that was logged for the operation.

The IBS mechanism is split into two parts: instruction fetch performance controlled by [MSRC001\\_1030 \[IBS Fetch Control \(IbsFetchCtl\)\]](#); and instruction execution performance controlled by [MSRC001\\_1033 \[IBS Execution Control \(IbsOpCtl\)\]](#). Instruction fetch sampling provides information about instruction TLB and instruction cache behavior for fetched instructions. Instruction execution sampling provides information about micro-op execution behavior. The data collected for instruction fetch performance is independent from the data collected for instruction execution performance. Support for the IBS feature is indicated by the [CPUID Fn8000\\_0001\\_ECX\[IBS\]](#).

Instruction fetch performance is profiled by recording the following performance information for the tagged instruction fetch:

- If the instruction fetch completed or was aborted. See [MSRC001\\_1030](#).
- The number of clock cycles spent on the instruction fetch. See [MSRC001\\_1030](#).
- If the instruction fetch hit or missed the IC, hit/missed in the L1 and L2 TLBs, and page size. See [MSRC001\\_1030](#).
- The linear address, physical address associated with the fetch. See [MSRC001\\_1031](#), [MSRC001\\_1032](#).

Instruction execution performance is profiled by tagging one micro-op associated with an instruction. Instructions that decode to more than one micro-op return different performance data depending upon which micro-op associated with the instruction is tagged. These micro-ops are associated with the RIP of the next instruction to retire. The following performance information is returned for the tagged micro-op:

- Branch and execution status for micro-ops. See [MSRC001\\_1035](#).
- Branch target address for branch micro-ops. See [MSRC001\\_103B](#).
- The logical address associated with the micro-op. See [MSRC001\\_1034](#).
- The linear and physical address associated with a load or store micro-op. See [MSRC001\\_1038](#), [MSRC001\\_1039](#).
- The data cache access status associated with the micro-op: DC hit/miss, DC miss latency, TLB hit/miss, TLB page size. See [MSRC001\\_1037](#).
- The number clocks from when the micro-op was tagged until the micro-op retires. See [MSRC001\\_1035](#).
- The number clocks from when the micro-op completes execution until the micro-op retires. See [MSRC001\\_1035](#).
- Source information for DRAM and MMIO. See [MSRC001\\_1036](#).

## 2.7 Configuration Space

PCI-defined configuration space was originally defined to allow up to 256 bytes of register space for each function of each device; these first 256 bytes are called base configuration space (BCS). It was expanded to support up to 4096 bytes per function; bytes 256 through 4095 are called extended configuration space (ECS). The processor includes configuration space registers located in both BCS and ECS. Processor configuration space is accessed through bus 0, devices 18h to 1Fh, where device 18h corresponds to node 0 and device 1Fh corresponds to node 7. See [2.7.3 \[Processor Configuration Space\]](#).

Configuration space is accessed by the processor through two methods:

- IO-space configuration: IO instructions to addresses CF8h and CFCh.
  - Enabled through [IOCF8\[ConfigEn\]](#), which allows access to BCS.
  - Access to ECS enabled through [MSRC001\\_001F\[EnableCf8ExtCfg\]](#).
  - Use of IO-space configuration can be programmed to generate GP faults through [MSRC001\\_0015\[IoCf-gGpFault\]](#).
  - SMI trapping for these accesses is specified by [MSRC001\\_0054 \[IO Trap Control \(SMI\\_ON\\_IO\\_TRAP\\_CTL\\_STS\)\]](#) and [MSRC001\\_00\[53:50\] \[IO Trap \(SMI\\_ON\\_IO\\_TRAP\\_\[3:0\]\)\]](#).
- MMIO configuration: configuration space is a region of memory space.
  - The base address and size of this range is specified by [MSRC001\\_0058 \[MMIO Configuration Base Address\]](#). The size is controlled by the number of configuration-space bus numbers supported by the system. Accesses to this range are converted configuration space as follows:
    - Address[31:0] = {0h, bus[7:0], device[4:0], function[2:0], offset[11:0]}.

The BIOS may use either configuration space access mechanism during boot. Before booting the OS, BIOS must disable IO access to ECS, enable MMIO configuration and build an ACPI defined MCFG table. BIOS ACPI code must use MMIO to access configuration space.

Per the link specification, BCS accesses utilize link addresses starting at FD\_FE00\_0000h and ECS accesses utilize link addresses starting at FE\_0000\_0000h.

### 2.7.1 MMIO Configuration Coding Requirements

MMIO configuration space accesses must use the uncacheable (UC) memory type.

Instructions used to read MMIO configuration space are required to take the following form:

```
mov eax/ax/al, any_address_mode;
```

Instructions used to write MMIO configuration space are required to take the following form:

```
mov any_address_mode, eax/ax/al;
```

No other source/target registers may be used other than eax/ax/al.

In addition, all such accesses are required not to cross any naturally aligned DW boundary. Access to MMIO configuration space registers that do not meet these requirements result in undefined behavior.

### 2.7.2 MMIO Configuration Ordering

Since MMIO configuration cycles are not serializing in the way that IO configuration cycles are, their ordering rules relative to posted may result in unexpected behavior.

Therefore, processor MMIO configuration space is designed to match the following ordering relationship that exists naturally with IO-space configuration: if a core generates a configuration cycle followed by a posted-write cycle, then the posted write is held in the processor until the configuration cycle completes. As a result, any unexpected behavior that might have resulted if the posted-write cycle were to pass MMIO configuration cycle is avoided.

### 2.7.3 Processor Configuration Space

The processor includes configuration space as described in [3 \[Registers\]](#). Accesses to unimplemented registers

of implemented functions are ignored: writes dropped; reads return 0. Accesses to unimplemented functions also ignored: writes are dropped; however, reads return all F's. The processor does not log any master abort events for accesses to unimplemented registers or functions.

Accesses to device numbers of devices not implemented in the processor are routed based on the configuration map registers. If such requests are master aborted, then the processor can log the event.

## 2.8 Northbridge (NB)

Each node includes a single northbridge that provides the interface to the local core(s), the interface to system memory, and the interface to system IO devices. The NB includes all power planes except VDD; see [2.5.1 \[Processor Power Planes And Voltage Control\]](#).

The NB is responsible for routing transactions sourced from cores and link to the appropriate core, cache, DRAM, or link. See [2.4.6 \[System Address Map\]](#).

### 2.8.1 NB Architecture

Major NB blocks are: System Request Interface (SRI), Memory Controller (MCT), DRAM Controllers (DCTs), and crossbar (XBAR). SRI interfaces with the core(s). MCT maintains cache coherency and interfaces with the DCTs; MCT maintains a queue of incoming requests called MCQ. XBAR is a switch that routes packets between SRI, MCT, and the link.

The MCT operates on physical addresses. Before passing transactions to the DCTs, the MCT converts physical addresses into *normalized* addresses that correspond to the values programmed into [D18F2x\[5C:40\]\\_dct\[3:0\] \[DRAM CS Base Address\]](#). Normalized addresses include only address bits within the DCTs' range.

### 2.8.2 NB Routing

#### 2.8.2.1 Address Space Routing

There are four main types of address space routed by the NB:

1. Memory space targeting system DRAM
2. Memory space targeting IO (MMIO)
3. IO space
4. Configuration space.

##### 2.8.2.1.1 DRAM and MMIO Memory Space

Memory space transactions provide the NB with the physical address, cacheability type, access type, and DRAM/MMIO destination type as specified in section [2.4.6.1.2 \[Determining The Access Destination for Core Accesses\]](#).

Memory-space transactions are handled by the NB as follows:

- IO-device accesses are compared against:
  - If the access matches [D18F1x\[2CC:2A0,1CC:180,BC:80\] \[MMIO Base/Limit\]](#), then the transaction is routed to the root complex;
  - Else, if the access matches [D18F1x\[17C:140,7C:40\] \[DRAM Base/Limit\]](#), then the access is routed to the DCT;
  - Else, the access is routed to the UMI.
- For core accesses the routing is determined based on the DRAM/MMIO destination:
  - If the destination is DRAM:
    - If the access matches [D18F1x\[17C:140,7C:40\] \[DRAM Base/Limit\]](#), then the transaction is routed

- to the DCT;
- Else, the access is routed to the UMI.
- If the destination is MMIO:
  - If the access matches the VGA-compatible MMIO address space and [D18F1xF4\[VE\]=1](#) then [D18F1xF4](#) describes how the access is routed and controlled;
  - Else, If the access matches [D18F1x\[2CC:2A0,1CC:180,BC:80\]](#) [MMIO Base/Limit], then the transaction is routed to the root complex;
  - Else, the access is routed to the UMI.

#### 2.8.2.1.2 IO Space

IO-space transactions from IO links or cores are routed as follows:

- If the access matches [D18F1x\[DC:C0\]](#) [IO-Space Base/Limit], then the transaction is routed to the root complex;
- Else, If the access matches the VGA-compatible IO address space and [D18F1xF4\[VE\]=1](#) then [D18F1xF4](#) describes how the access is routed and controlled.
- Else, the access is routed to the UMI.

#### 2.8.2.1.3 Configuration Space

Configuration-space transactions from IO links are master aborted. Configuration-space transactions from cores are routed as follows:

- If the access matches [D18F1x\[1DC:1D0,EC:E0\]](#) [Configuration Map], then the transaction is routed to the specified link;
- Else, the access is routed to link that contains compatibility (subtractive) address space.

### 2.8.2.1.3.1 Recommended Buffer Count Settings Overview

When changing from the recommended settings, see the register programming requirements in the definition of each register. Some chipsets may further optimize these settings for their platform. If values other than the recommended settings are used, see the register requirements in the definition of each register. [Table 13](#) defines commonly used terms for the following tables.

**Table 13: ONION Link Definitions**

| Term              | Definition                                                                                                                                                                      |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LinkGanged</b> | Ganged = 0.                                                                                                                                                                     |
| <b>IOMMU</b>      | Indicates the presence of an IOMMU device on the IOH. IOMMU uses the isochronous flow control channel. If an IOMMU is present, D18F0x[A4,84][IsocEn] must be set for all links. |
| <b>IFCM</b>       | Isochronous Flow Control Mode. IFCM = D18F0x[A4,84][IsocEn].                                                                                                                    |

### 2.8.3 Memory Scrubbers

The processor includes memory scrubbers specified in [D18F3x58](#), [D18F3x5C](#), and [D18F3x60](#). The scrubbers ensure that all cachelines in memory within or connected to the processor are periodically read and, if correctable errors are discovered, they are corrected.

For recommendations on scrub rates, see [2.15.1.8 \[Scrub Rate Considerations\]](#).

The scrub rate is specified as the time between successive scrub events. A scrub event occurs when a line of memory is checked for errors; the amount of memory that is checked varies based on the memory block (see field descriptions).

The time required to fully scrub the memory of a node is determined as:

- $\text{Time} = ((\text{memory size in bytes})/64) * (\text{Scrub Rate})$ .
- E.g. If a node contains 1GB of system memory and  $\text{DramScrub} = 5.24 \text{ ms}$ , then all of the system memory of the node is scrubbed about once every 23 hours.

## 2.9 DRAM Controllers (DCTs)

The processor includes two DRAM controllers (DCTs), named DCT0 and DCT3. Each DCT controls one 64-bit DDR3 DRAM channel as shown in the following table. Software must not attempt to configure “DCT1” or “DCT2”.

**Table 14: DCT Channel Ctrl Map**

| Channel   |      |      |           |
|-----------|------|------|-----------|
| DCT0      | DCT2 | DCT1 | DCT3      |
| Channel A | -    | -    | Channel B |

The following restrictions limit the DIMM types and configurations supported by the DCTs:

- All DIMMs connected to the processor are required to operate at the same MEMCLK frequency.
- Registered DIMMs are not supported.
- LR-DIMMs are not supported.
- Quad rank DIMMs are not supported.
- x4(by 4) DRAM devices are not supported.
- ECC DIMMs are supported on FP3 package
  - Mixing of ECC and non-ECC DIMMs within a system is not supported
- ECC DIMMs are not supported on FM2r2 package
- GDDR5 memory is not supported.

### 2.9.1 Common DCT Definitions

**Table 15: DCT Definitions**

| Term                   | Definition                                                                                                                                                                                                                                                                                                                                                                                                       |      |             |     |            |     |                              |     |                               |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------------|-----|------------|-----|------------------------------|-----|-------------------------------|
| <b>any</b>             | Any: <a href="#">SR</a> or <a href="#">DR</a> .                                                                                                                                                                                                                                                                                                                                                                  |      |             |     |            |     |                              |     |                               |
| <b>AutoSelfRefresh</b> | SPDByte[31][2] of the DIMM being configured.                                                                                                                                                                                                                                                                                                                                                                     |      |             |     |            |     |                              |     |                               |
| <b>DataMaskMbType</b>  | Motherboard type for processor Data Mask pins.<br><table> <tr> <th>Bits</th><th>Description</th></tr> <tr> <td>00b</td><td>No connect</td></tr> <tr> <td>01b</td><td>Pins are routed per DM rules</td></tr> <tr> <td>10b</td><td>Pins are routed per DQS rules</td></tr> </table>                                                                                                                                | Bits | Description | 00b | No connect | 01b | Pins are routed per DM rules | 10b | Pins are routed per DQS rules |
| Bits                   | Description                                                                                                                                                                                                                                                                                                                                                                                                      |      |             |     |            |     |                              |     |                               |
| 00b                    | No connect                                                                                                                                                                                                                                                                                                                                                                                                       |      |             |     |            |     |                              |     |                               |
| 01b                    | Pins are routed per DM rules                                                                                                                                                                                                                                                                                                                                                                                     |      |             |     |            |     |                              |     |                               |
| 10b                    | Pins are routed per DQS rules                                                                                                                                                                                                                                                                                                                                                                                    |      |             |     |            |     |                              |     |                               |
| <b>Ddr3Mode</b>        | The DRAM controller and the phy are configured for DDR3 mode. Note: this mode may not be supported by this processor. See section 2.9, or consult processor data sheet to determine which modes are supported. See <a href="#">D18F2x78_dct[3:0][DramType]</a> , <a href="#">D18F2x9C_x00[F,3:0]0_[F,B:0]04A_dct[3:0][MajorMode]</a> , and <a href="#">D18F2x9C_x00[F,8:0]1_[F,B:0]04A_dct[3:0][MajorMode]</a> . |      |             |     |            |     |                              |     |                               |
| <b>DdrRate</b>         | The DDR data rate (MT/s) as specified by (if Ddr3Mode then <a href="#">D18F2x94_dct[3:0][MemClkFreq]</a> and <a href="#">D18F2x2E0_dct[3:0][M1MemClkFreq]</a> ).                                                                                                                                                                                                                                                 |      |             |     |            |     |                              |     |                               |
| <b>DeviceWidth</b>     | DDR3 SPDByte[7][2:0] of the DIMM being configured.                                                                                                                                                                                                                                                                                                                                                               |      |             |     |            |     |                              |     |                               |
| <b>DIMM</b>            | The DIMM being configured                                                                                                                                                                                                                                                                                                                                                                                        |      |             |     |            |     |                              |     |                               |

**Table 15: DCT Definitions**

| Term                             | Definition                                                                                                                                                                                                      |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DIMM0</b>                     | DIMM slots 0-n. The DIMMs on each channel are numbered from 0 to n where                                                                                                                                        |
| <b>DIMM1</b>                     | DIMM0 is the DIMM closest to the processor on that channel and DIMMn is the DIMM farthest from the processor on that channel.                                                                                   |
| <b>DimmsPopulated</b>            | The number of DIMMs populated per channel plus rows of <a href="#">Solder-down DRAM</a> devices.                                                                                                                |
| <b>DR</b>                        | Dual Rank                                                                                                                                                                                                       |
| <b>DramCapacity</b>              | DDR3 SPDByte[4][3:0] of the DIMM being configured.                                                                                                                                                              |
| <b>ExtendedTemperature-Range</b> | DDR3 SPDByte[31][0] of the DIMM being configured.                                                                                                                                                               |
| <b>Gddr5Mode</b>                 | The DRAM controller and the phy are configured for GDDR5 mode. Note: this mode may not be supported by this processor. See section 2.9, or consult processor data sheet to determine which modes are supported. |
| <b>MaxDct</b>                    | The range of values supported by <a href="#">D18F1x10C[DctCfgSel]</a> for registers with the mnemonic <a href="#">D18F2xXXX_dct[MaxDct:0]</a> . MaxDct = 3. See 2.9.3 [DCT Configuration Registers].            |
| <b>MaxDctMstr</b>                | The range of values supported by <a href="#">D18F1x10C[DctCfgSel]</a> for registers with the mnemonic <a href="#">D18F2x[B,0]9[C,8]_xXXXX_XXXX_dct[MaxDctMstr:0]</a> . See 2.9.3 [DCT Configuration Registers]. |
| <b>MRS</b>                       | JEDEC defined DRAM Mode Register Set.                                                                                                                                                                           |
| <b>NP</b>                        | No DIMM populated                                                                                                                                                                                               |
| <b>NumDimmSlots</b>              | The number of motherboard DIMM slots per channel plus rows of <a href="#">Solder-down DRAM</a> devices                                                                                                          |
| <b>NumRanks</b>                  | DDR3 SPDByte[7][5:3] of the DIMM being configured, or the number of ranks soldered down.                                                                                                                        |
| <b>Rank</b>                      | The rank being configured                                                                                                                                                                                       |
| <b>RankMap</b>                   | DDR3 SPDByte[63][0] of the DIMM being configured. .                                                                                                                                                             |
| <b>RowAddrBits</b>               | DDR3 SPDByte[5][5:3] of the DIMM being configured.                                                                                                                                                              |
| <b>Solder-down DRAM</b>          | DRAM devices soldered directly to the motherboard.                                                                                                                                                              |
| <b>SODIMM</b>                    | DCT is configured for SODIMM if ( <a href="#">D18F2x90_dct[3:0][UnbuffDimm]==1</a> ) and SODIMMs are populated.                                                                                                 |
| <b>SPD</b>                       | Serial Presence Detect. In the case of DRAMs soldered on the platform, this refers to a virtual representation of the DRAM vendors' data sheets.                                                                |
| <b>SR</b>                        | Single Rank                                                                                                                                                                                                     |
| <b>UDIMM</b>                     | DCT is configured for UDIMM if ( <a href="#">D18F2x90_dct[3:0][UnbuffDimm]==1</a> ) and UDIMMs are populated.                                                                                                   |

## 2.9.2 DCT Frequency Support

The tables below list the maximum DIMM speeds supported by the processor for different configurations. The motherboard should comply with the relevant AMD socket motherboard design guideline (MBDG) to achieve the rated speeds. In cases where MBDG design options exist, lower-quality options may compromise the maximum achievable speed; motherboard designers should assess the tradeoffs.

The FP3 package supports two different voltage levels on the VDDR rail. At the 1.05V nominal setting, the maximum speed of 2133 can be supported while at the 0.95V setting, the maximum speed supported is 1600. See 2.11.3.1 for its effect on PCIe data rate.

Table 16: DDR3 **UDIMM** Maximum Frequency Support for FM2r2 package

| Num-DimmSlots | DimmsPopulated | DRAM |    | Frequency <sup>1</sup> (MT/s) |       |       |
|---------------|----------------|------|----|-------------------------------|-------|-------|
|               |                | SR   | DR | 1.5V                          | 1.35V | 1.25V |
| 1             | 1              | 1    | -  | 2133                          | 1866  | 1600  |
|               |                | -    | 1  | 1866                          | 1600  | 1600  |
| 2             | 1              | 1    | -  | 1866                          | 1600  | 1333  |
|               |                | -    | 1  | 1866                          | 1600  | 1333  |
|               | 2              | 2    | -  | 1866                          | 1600  | 1333  |
|               |                | 1    | 1  | 1600                          | 1333  | 1333  |
|               |                | -    | 2  | 1600                          | 1333  | 1333  |
|               |                |      |    |                               |       |       |

1. Population restrictions (including the order for partially populated channels) may apply. Num-DimmSlots and DimmsPopulated are per channel.

2.

Table 17: DDR3 **UDIMM** Maximum Frequency Support for FP3 package

| Num-DimmSlots | DimmsPopulated | DRAM |    | Frequency <sup>1</sup> (MT/s) |       |       |
|---------------|----------------|------|----|-------------------------------|-------|-------|
|               |                | SR   | DR | 1.5V                          | 1.35V | 1.25V |
| 1             | 1              | 1    | -  | 2133                          | 1866  | 1600  |
|               |                | -    | 1  | 1866                          | 1600  | 1600  |
| 2             | 1              | 1    | -  | 2133                          | 1866  | 1600  |
|               |                | -    | 1  | 1866                          | 1600  | 1600  |
|               | 2              | 2    | -  | 1866                          | 1600  | 1333  |
|               |                | 1    | 1  | 1600                          | 1333  | 1333  |
|               |                | -    | 2  | 1600                          | 1333  | 1333  |
|               |                |      |    |                               |       |       |

1. Population restrictions (including the order for partially populated channels) may apply. Num-DimmSlots and DimmsPopulated are per channel.

2.

Table 18: DDR3 **SODIMM** Maximum Frequency Support for FM2r2 package

| Num-DimmSlots | DimmsPopulated | DRAM |    | Frequency <sup>1</sup> (MT/s) |       |       |
|---------------|----------------|------|----|-------------------------------|-------|-------|

|---------------|----------------|------|----|-------------------------------|-------|-------|
|               |                | SR   | DR | 1.5V                          | 1.35V | 1.25V |
| 2             | 1              | 1    | -  | 1600                          | 1600  | 1333  |
|               |                | -    | 1  | 1600                          | 1600  | 1333  |
|               | 2              | 2    | -  | 1600                          | 1333  | 1333  |
|               |                | 1    | 1  | 1333                          | 1333  | 1333  |
|               |                | -    | 2  | 1333                          | 1333  | 1333  |

1.

Population restrictions (including the order for partially populated channels) may apply. Num-DimmSlots and DimmsPopulated are per channel.

2.

Table 19: DDR3 SODIMM Maximum Frequency Support for FP3 package

| Num-DimmSlots | DimmsPopulated | DRAM |    | Frequency <sup>1</sup> (MT/s) |       |       |
|---------------|----------------|------|----|-------------------------------|-------|-------|
|               |                | SR   | DR | 1.5V                          | 1.35V | 1.25V |
| 1             | 1              | 1    | -  | 2133                          | 1866  | 1600  |
|               |                | -    | 1  | 1866                          | 1600  | 1600  |
| 2             | 1              | 1    | -  | 1600                          | 1600  | 1333  |
|               |                | -    | 1  | 1600                          | 1600  | 1333  |
|               | 2              | 2    | -  | 1600                          | 1333  | 1333  |
|               |                | 1    | 1  | 1333                          | 1333  | 1333  |
|               |                | -    | 2  | 1333                          | 1333  | 1333  |
|               |                |      |    |                               |       |       |

1. Population restrictions (including the order for partially populated channels) may apply. Num-DimmSlots and DimmsPopulated are per channel.

2.

### 2.9.3 DCT Configuration Registers

There are multiple types of DCT configuration registers:

- Registers for which there is one instance for all DCT's. E.g. [D18F2xA4](#).
- Registers for which there is one instance per DCT. E.g. [D18F2x78\\_dct\[3:0\]](#).
  - For [D18F2x78\\_dct\[x\]](#), x=[D18F1x10C\[DctCfgSel\]](#); see [D18F1x10C\[DctCfgSel\]](#).
  - The syntax for this register type is described by example as follows:
    - [D18F2x78\\_dct\[3:0\]](#) refers to all instances of the [D18F2x78](#) register.
    - [D18F2x78\\_dct\[1\]](#) refers to the [D18F2x78](#) register instance for DCT1.
- Registers for which there is one instance per NbPstate use [D18F1x10C\[NbPsSel\]](#) for software accesses.
  - [D18F2x210\\_dct\[3:0\]\\_nbp\[3:0\]](#) refers to all instances of the [D18F2x210](#) register.
  - [D18F2x210\\_dct\[3:0\]\\_nbp\[1\]](#) refers to the register for Nb P-state 1 of any or all DCTs.
- Registers for which there is one instance per memory P-state use [D18F1x10C\[MemPsSel\]](#) for software accesses. The syntax for this register type is described by example as follows:
  - [D18F2x2E8\\_dct\[3:0\]\\_mp\[1:0\]](#) refers to all instances of the [D18F2x2E8](#) register.

- D18F2x2E8\_dct[3:0]\_mp[1] refers to the register for memory P-state 1 of either or both DCTs.

In [Ddr3Mode](#), the DCT controls 64-bits of data. The phy registers of a 64-bit phy channel are programmed through a single DCT master by setting [D18F1x10C](#)[DctCfgSel] to the DCT master as shown in [Table 14](#).

## 2.9.4 DDR Pad to Processor Pin Mapping

The relationship of pad drivers to processor pins varies by package as shown in the following table.

**Table 20: Package pin mapping**

| Pad          | Pin <sup>1</sup>    |             |     |
|--------------|---------------------|-------------|-----|
|              | FS2 (not supported) | FM2r2       | FP3 |
| MEMCLK0_H[0] | MA_CLK_H[0]         |             |     |
| MEMCLK0_H[1] | MA_CLK_H[1]         |             |     |
| MEMCLK0_H[2] | NC                  | MA_CLK_H[2] |     |
| MEMCLK0_H[3] | NC                  | MA_CLK_H[3] |     |
| MEMCLK0_H[4] | NC                  |             |     |
| MEMCLK1_H[0] | MB_CLK_H[0]         |             |     |
| MEMCLK1_H[1] | MB_CLK_H[1]         |             |     |
| MEMCLK1_H[2] | NC                  | MB_CLK_H[2] |     |
| MEMCLK1_H[3] | NC                  | MB_CLK_H[3] |     |
| MEMCLK1_H[4] | NC                  |             |     |
| MEMCS0_L[0]  | MA0_CS_L[0]         |             |     |
| MEMCS0_L[1]  | MA0_CS_L[1]         |             |     |
| MEMCS0_L[2]  | NC                  | MA1_CS_L[0] |     |
| MEMCS0_L[3]  | NC                  | MA1_CS_L[1] |     |
| MEMCS0_L[4]  | NC                  |             |     |
| MEMCS0_L[5]  | NC                  |             |     |
| MEMCS0_L[6]  | NC                  |             |     |
| MEMCS0_L[7]  | NC                  |             |     |
| MEMCS1_L[0]  | MB0_CS_L[0]         |             |     |
| MEMCS1_L[1]  | MB0_CS_L[1]         |             |     |
| MEMCS1_L[2]  | NC                  | MB1_CS_L[0] |     |
| MEMCS1_L[3]  | NC                  | MB1_CS_L[1] |     |
| MEMCS1_L[4]  | NC                  |             |     |
| MEMCS1_L[5]  | NC                  |             |     |
| MEMCS1_L[6]  | NC                  |             |     |
| MEMCS1_L[7]  | NC                  |             |     |
| MEMODT0[0]   | MA0_ODT[0]          |             |     |
| MEMODT0[1]   | MA0_ODT[1]          |             |     |
| MEMODT0[2]   | NC                  | MA1_ODT[0]  |     |

**Table 20: Package pin mapping**

|                                                                                                                                                                                                                                                         |            |            |

| 1. For differential pins, only positive polarity pins are shown; negative polarity pins have corresponding mapping and are controlled by the same CSR field.<br>NC = Not connected. BIOS should tri-state or disable the pad for maximum power savings. |            |            |

### 2.9.4.1 DDR Chip to Pad Mapping

The relationship of chip to pad drivers is shown in the following table. BIOS should disable or power down unused chips for maximum power savings.

**Table 21: DDR Chip to pad mapping (DDR3 Mode)**

| Chiplet | Group | Pad Number <sup>1</sup> | Pad <sup>2</sup>                                                                         |

| <p>1. Pad number is the logical address of a CSR addressable timing or impedance control.<br/> <a href="#">D18F2x9C_x00[F,3:0]0_0009_dct[3:0][HiAddrMode] = 0.</a></p> <p>2. Only channel A is shown. Channel B is similar.</p> <p>3. Pad column shows pads only for Data chip 0. Data chips [7:1] are repeated with sequential DQ/DQS/DM pin numbers.</p> <p>4. MEMDQSDM functions as DM when using unbuffered DIMMs. MEMDQS_H is the positive polarity of the “lower nibble” DQS pad used for all devices.</p> |                         |           |                                                                                                  |

### 2.9.5 DRAM Controller Direct Response Mode

The DCT supports direct response mode for responding to a cache line fill request before the DCT is initialized. In direct response mode, the target DCT responds to a cache line fill request by returning 64 bytes of all

ones without issuing a read transaction on the DRAM bus. The BIOS uses this feature to allocate cache lines for temporary data storage. The controller exits direct response mode when either [D18F2x78\\_dct\[3:0\]](#)[Chan-Val] is set to 1. See [2.3.3 \[Using L2 Cache as General Storage During Boot\]](#).

### 2.9.6 DRAM Data Burst Mapping

DRAM requests are mapped to data bursts on the DDR bus in the following order:

- When [D18F2x110](#)[DctDatIntLv] = 0, a 64 B request is mapped to each of the eight sequential data beats as QW0, QW1...QW7.
- When [D18F2x110](#)[DctDatIntLv] = 1, the order of cache data to QW on the bus is the same except that even and odd bits are interleaved on the DRAM bus as follows:
  - For every 8 bytes in the cache line, even bits map to QW0, QW2, QW4, and QW6 on the DRAM bus.
  - For every 8 bytes in the cache line, odd bits map to QW1, QW3, QW5, and QW7 on the DRAM bus.

## 2.9.7 SOC Specific Definitions

**Table 22: DCT Definitions**

| Term                    | Definition                                                             |
|-------------------------|------------------------------------------------------------------------|
| <b>GraphicsDC</b>       | Graphics downcore.                                                     |
| <b>Solder-down DRAM</b> | DRAM devices soldered directly to the motherboard.                     |
| <b>SRAMmsgBlk</b>       | SRAM message block. See <a href="#">2.9.8.3 [SRAM Message Block]</a> . |

## 2.9.8 PMU

The processor includes a phy micro-controller unit (PMU) used for training the DDR data bus during boot. BIOS communicates with the PMU using one of two methods.

- Mailbox: BIOS waits for upstream messages from the PMU for action synchronization or for status messages.
  - A 16-bit mailbox exists for upstream messages. See [2.9.8.1](#). Only the lower 8-bits are used. BIOS may safely ignore the upper 8-bits of the message.
  - A 16-bit mailbox exists for upstream data transfer. See [2.9.8.2](#).
- SRAM: BIOS may read or write the memory used by the PMU to send or receive complex message data. The PMU must be halted or in the reset state for BIOS to access PMU SRAM.

### 2.9.8.1 mboxUSPend

To wait for an upstream message BIOS does the following:

1. Wait until `D18F2x9C_x0002_0004_dct[3:0][UsRdy] == 0`.
2. Read `D18F2x9C_x0002_0032_dct[3:0][Message]`. See [Table 23](#) for a list of message names and values.
3. Program `D18F2x9C_x0002_0033_dct[3:0][Rdy] = 1`.

See [2.9.9.5](#) for related information.

**Table 23: US Mailbox 1 Messages for DDR3**

| Name         | <code>D18F2x9C_x0002_0032_dct[3:0][Message]</code> | Description                      |
|--------------|----------------------------------------------------|----------------------------------|
| DevInit      | 00h                                                | PMU has completed DevInit.       |
| TrainWrLvl   | 01h                                                | PMU has completed TSTAGE_WrLvl   |
| TrainRxEn    | 02h                                                | PMU has completed TSTAGE_RxEn    |
| TrainRdDqs1D | 03h                                                | PMU has completed TSTAGE_RdDqs1D |
| TrainWrDq1D  | 04h                                                | PMU has completed TSTAGE_WrDq1D  |
| TrainRd2D    | 05h                                                | PMU has completed TSTAGE_Rd2D    |
| TrainWr2D    | 06h                                                | PMU has completed TSTAGE_Wr2D.   |

**Table 23: US Mailbox 1 Messages for DDR3**

| Name      | D18F2x9C_x0002_0032_dct[3:0][Message] | Description                                                                                                     |
|-----------|---------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| PMUQEmpty | 07h                                   | PMU has completed all of its SequenceCtl tasks and is in a power-gated idle state.                              |
| US2MsgRdy | 08h                                   | PMU is ready to stream a message through US mailbox 2.                                                          |
| FAIL      | 0FFh                                  | PMU has encountered an error which requires requester to abort waiting for remaining pending upstream messages. |

### 2.9.8.2 mboxUS2Pend

To receive a block of data through US mailbox 2, BIOS does the following:

1. Wait until [D18F2x9C\\_x0002\\_0004\\_dct\[3:0\]\[Us2Rdy\]](#)==0.
2. Read [D18F2x9C\\_x0002\\_0034\\_dct\[3:0\]\[Message\]](#). The first item received is the COUNT.
3. Program [D18F2x9C\\_x0002\\_0035\\_dct\[3:0\]\[Rdy\]](#) = 1.
4. Decrement COUNT and loop to step 1 until COUNT==1.

### 2.9.8.3 SRAM Message Block

The SRAM message block is used to pass information from BIOS to PMU and vice-versa. BIOS accesses the SRAM message block through [D18F2x9C\\_x0005\\_\[0BFF:0000\]\\_dct\[3:0\]](#).

**Table 24: SRAM Message Block for DDR3**

| Name       | Memory P-state <sup>1</sup> | Location <sup>2</sup> | Input for | Output of | Description                                                                                                                                                                        |

### 2.9.9 DCT/DRAM Initialization and Resume

DRAM initialization involves several steps in order to configure the DRAM controllers and the DRAM, and to tune the DRAM channel for optimal performance. DRAM resume requires several steps to configure the DCTs to properly resume from the S3 state. The following sequence describes the steps needed after a reset for initialization or resume:

- To disable an unused DRAM channel see [2.9.9.8](#).
1. Configure the DDR supply voltage regulator. See [2.9.9.1](#).
  2. NB P-state specific initialization.
    - A. Program the DCT configuration registers which contain multiple internal copies for each NB P-state. See [D18F1x10C\[NbPsSel\]](#).
    - B. Force NB P-state to NBP0. See [2.5.4.1.3.2](#)
  3. DDR phy initialization. See [2.9.9.2](#).
  4. If BIOS is booting from an unpowered state (ACPI S4, S5 or G3), then it performs the following:
    - A. Program DRAM controller general configuration, for both memory P-states. See [2.9.9.3](#).
    - B. Program DCT specific configuration for training, for both memory P-states. See [2.9.9.4](#).
    - C. Program the remaining DCT registers not covered by an explicit sequence dependency.
    - D. Program [D18F2x9C\\_x0002\\_0060\\_dct\[3:0\]\[MemReset\\_L\]](#)=0.
    - E. Program [D18F2x9C\\_x0002\\_000B\\_dct\[3:0\]](#)=0004h.
    - F. Program [D18F2x9C\\_x0002\\_000B\\_dct\[3:0\]](#)=0000h.
    - G. Perform DRAM device initialization and data training. See [2.9.9.5](#).
    - H. Enable phy auto-calibration. See [2.9.9.2.8.3](#).
    - I. Synchronous channel initialization. See [2.9.9.7](#).
    - J. Program [D18F2x90\\_dct\[3:0\]\[ExitSelfRef\]](#)=1. Wait for [D18F2x90\\_dct\[3:0\]\[ExitSelfRef\]](#)==0. Wait  $T_{ref} \times 2$ .
    - K. Program [D18F2x78\\_dct\[3:0\]\[ChanVal\]](#)=1.
    - L. NB P-state specific training. For each NB P-state from NBP0 to [D18F5x170\[NbPstateMaxVal\]](#):
      - a. Force the NB P-state. See [2.5.4.1.3.2](#).
      - b. MaxRdLatency training. See [2.9.9.6.1](#).
    - M. Program DCT specific configuration for normal operation, for both memory P-states. See [2.9.9.4](#).
    - N. Program DRAM phy for power savings. See [2.9.9.9](#).
  5. If BIOS is resuming the platform from S3 state, then it performs the following:
    - A. Restore all DCT and phy registers that were programmed during the first boot from non-volatile storage. See [2.9.9.3](#), [2.9.9.4](#), and [2.9.9.9](#) for a review of registers.
    - B. Restore the trained delayed values from nonvolatile storage. See [2.9.9.2.10](#).
    - C. Program [D18F2x9C\\_x0002\\_0060\\_dct\[3:0\]\[MemReset\\_L\]](#)=1.
    - D. Program [D18F2x9C\\_x0002\\_000B\\_dct\[3:0\]](#)=0004h.
    - E. Program [D18F2x9C\\_x0002\\_000B\\_dct\[3:0\]](#)=0000h.
    - F. Fence the CalOnce. See [2.9.9.2.8.2](#).
    - G. Enable phy auto-calibration. See [2.9.9.2.8.3](#).
    - H. Synchronous channel initialization. See [2.9.9.7](#).
    - I. Program [D18F2x90\\_dct\[3:0\]\[ExitSelfRef\]](#)=1. Wait for [D18F2x90\\_dct\[3:0\]\[ExitSelfRef\]](#)==0
    - J. Program [D18F2x78\\_dct\[3:0\]\[ChanVal\]](#)=1.
  6. Release NB P-state force. See [2.5.4.1.3.2](#).

The DRAM subsystem is ready for use.

### 2.9.9.1 Low Voltage

For DDR3 devices, the processor supports JEDEC defined 1.5V, 1.35V and 1.25V devices

Platforms supporting low voltage devices should power up VDDIO at 1.35V. BIOS should not operate DIMMs at voltages higher than supported. For DDR3 this is indicated by SPD Byte 6: Module Nominal Voltage, VDD.

BIOS should consult vendor data sheets for the supply voltage regulator programming requirements. On supported platforms, BIOS must take steps to configure the supply voltage regulators as follows:

1. Read the [SPD](#) of all devices within the programmable VDDIO domain and check all of the defined bits within the SPD byte to determine the common operating voltages.
2. Configure VDDIO to match the lowest common supported voltage based on the SPD values.
  - If the DIMMs do not specify a common operating voltage then BIOS must take platform vendor defined action to notify the end user of the mismatch and to protect DIMMs from damage.
3. Additional derating of the DDR speed may be necessary for reliable operation at lower voltage.

### 2.9.9.2 DDR Phy Initialization

The BIOS initializes the phy and the internal interface from the DCT to the phy, after each reset and for each time a MEMCLK frequency change is made.

BIOS obtains size, loading, and frequency information about the DIMMs and channels using SPDs prior to phy initialization. BIOS then performs the following actions:

1. Program [D18F2x9C\\_x0002\\_0099\\_dct\[3:0\]\[PmuReset,PmuStall\]](#) = 1,1.
2. Program [D18F2x9C\\_x0002\\_000E\\_dct\[3:0\]\[PhyDisable\]](#)=0.
3. According to the type of DRAM attached, program the following:
  - Program [D18F2x9C\\_x00FF\\_F04A\\_dct\[3:0\]](#) = {000000h,0b,MajorMode,0h}. This is a “super-broadcast” to all instances. See:
    - [D18F2x9C\\_x00\[F,3:0\]0\\_\[F,B:0\]04A\\_dct\[3:0\]\[MajorMode\]](#)
    - [D18F2x9C\\_x00\[F,8:0\]1\\_\[F,B:0\]04A\\_dct\[3:0\]\[MajorMode\]](#)
    - [D18F2x9C\\_x0009\\_004A\\_dct\[3:0\]\[MajorMode\]](#)
  - [D18F2x9C\\_x00\[F,8:0\]1\\_\[F,B:0\]05F\\_dct\[3:0\]\[G5Mode\]](#) This register is optimally programmed during data bus driver configuration in [2.9.9.2.5](#) instead of at this time.
  - [D18F2x9C\\_x0002\\_000E\\_dct\[3:0\]\[G5\\_Mode\]](#)
  - [D18F2x9C\\_x0002\\_0098\\_dct\[3:0\]\[CalG5D3\]](#).
4. Program general phy static configuration. See [2.9.9.2.1](#).
5. Phy Voltage Level Programming. See [2.9.9.2.2](#).
6. Program auto-calibration. See [2.9.9.2.8](#).
7. Program DRAM channel frequency. See [2.9.9.2.3](#).
8. Program default CAD bus values. See [2.9.9.2.4](#).
9. Program default data bus values. See [2.9.9.2.5](#).
10. Program FIFO pointer init values. See [2.9.9.2.6](#).
11. Program predriver values. See [2.9.9.2.7](#).
12. Program [D18F2x9C\\_x0002\\_0033\\_dct\[3:0\]\[Rdy\]](#) = 1.
13. Program [D18F2x9C\\_x0002\\_0035\\_dct\[3:0\]\[Rdy\]](#) = 1.

#### 2.9.9.2.1 Phy General Configuration

BIOS programs the following according to the static configuration:

- Program D18F2x9C\_x01F1\_F045\_dct[3:0]=0040h.
  - See D18F2x9C\_x0[3,1:0][F,8:0]1\_[F,7:0]045\_dct[3:0].
- If Ddr3Mode program D18F2x9C\_x00F4\_00E[7:0]\_dct[3:0].
- Program D18F2x9C\_x00F0\_0015\_dct[3:0][VrefFilt], D18F2x9C\_x00F1\_0015\_dct[3:0][VrefFilt], D18F2x9C\_x00F2\_0015\_dct[3:0][VrefFilt].
- Program D18F2x9C\_x00[F,8:0]1\_0016\_dct[3:0].

BIOS programs the following for maximum power savings prior to training:

- Program D18F2x9C\_x03F6\_F04E\_dct[] = 0B00h.
  - See D18F2x9C\_x00[F,3:0]0\_[F,B:0]04E\_dct[3:0] and D18F2x9C\_x00[F,8:0]1\_[F,B:0]04E\_dct[3:0].
- Program D18F2x9C\_x00F0\_001A\_dct[] (undocumented) = 0022h.
- Program D18F2x9C\_x00F1\_001A\_dct[] (undocumented) = 0033h.
- Program D18F2x9C\_x0002\_001A\_dct[] (undocumented) = 0001h.
- Program D18F2x9C\_x0002\_005B\_dct[3:0] = 0001h.
- Program D18F2x9C\_x00F1\_F051\_dct[] = 0152h.
  - See D18F2x9C\_x00[F,8:0]1\_[F,B:0]051\_dct[3:0].

### 2.9.9.2.2 Phy Voltage Level Programming

BIOS programs the following according to the desired phy VDDIO voltage level:

1. Program D18F2x9C\_x0002\_0098\_dct[3:0][CalCmptrResTrim].

See 2.9.9.1 [Low Voltage].

### 2.9.9.2.3 DRAM Channel Frequency

BIOS programs the DCT and the phy according to the data rate. BIOS must ensure that the DCT and the phy operate at a matched rate prior to normal operations. See D18F2x94\_dct[3:0][MemClkFreq], D18F2x2E0\_dct[3:0][M1MemClkFreq].

To program a new rate in the phy:

1. Program D18F2x9C\_x0002\_0093\_dct[3:0][PllRegWaitTime] = 04Bh.
2. Program D18F2x9C\_x0002\_0089\_dct[3:0][PllLockTime] = 190h.
3. Program D18F2x9C\_x0002\_0000\_dct[3:0][PllMultDiv].
4. Program D18F2x9C\_x0002\_0080\_dct[3:0][PMUClkDiv].
  - See D18F2x9C\_x0[1:0]02\_0080\_dct[3:0].
5. Program D18F2x9C\_x0002\_0001\_dct[3:0][PllMultDiv] = '667 MT/s'.
6. Program D18F2x9C\_x0102\_0080\_dct[3:0][PMUClkDiv].
  - See D18F2x9C\_x0[1:0]02\_0080\_dct[3:0].

The new settings will take effect after BIOS or the DCT requests a memory P-state change request via D18F2x9C\_x0002\_000B\_dct[3:0]. See 2.9.9 [DCT/DRAM Initialization and Resume].

### 2.9.9.2.4 DRAM CAD Bus Configuration

This section describes the settings required for programming the timing and drive settings on the command and address pins. The following tables document the CAD bus values on a per channel basis. DIMM0 is the DIMM closest to the processor on that channel and DIMM1 is the DIMM farthest from the processor on that channel. DIMMs must be populated from farthest slot to closest slot to the processor on a per channel basis (when a daisy chain topology is used). Populations that are not shown in these tables are not supported. These tables document the optimal settings for motherboards which meet the relevant motherboard design guidelines.

- Only the value for a single control unit register is described. The values in the tables should be broadcast to all instances of registers of the same control unit type, unless otherwise noted.

Table 25: BIOS Recommendations for DDR3 SO-DIMM CAD bus configuration

| Condition              |                   |                 |                 |                 | D18F2x94_dc[3:0]<br>[SlowAccessMode] | {000000000b<br>,AddrCmd-<br>Setup[5:0],00b<br>,CsOdt-<br>Setup[5:0],<br>00b, Cke-<br>Setup[5:0]} | D18F2x9C_x0[3,1:0][F,3:0]0_[F,B:0]041_dc[3:0]<br>[DrvStrenN] <sup>2</sup> for CKE | D18F2x9C_x0[3,1:0][F,3:0]0_[F,B:0]041_dc[3:0]<br>[DrvStrenN] <sup>2</sup> for CS and ODT | D18F2x9C_x0[3,1:0][F,3:0]0_[F,B:0]041_dc[3:0]<br>[DrvStrenN] <sup>2</sup> for AddrCmd | D18F2x9C_x0[3,1:0][F,3:0]0_[F,B:0]041_dc[3:0]<br>[DrvStrenN] <sup>2</sup> for CLK |

| 1. BIOS writes the values for AddrCmdSetup, CsOdtSetup, and CkeSetup into the SRAMMsgBlk for each memory P-state.<br>2. BIOS programs DrvStrenP = DrvStrenN for each instance. |                   |                 |                 |                 |                                       |                                                                                                   |                                                                                    |                                                                                           |                                                                                        |                                                                                    |

### 2.9.9.2.5 DRAM Data Bus Configuration

This section describes the settings required for programming the drive settings and slew rates on the data bus pins. The following tables document the data bus values on a per channel basis. DIMM0 is the DIMM closest to the processor on that channel and DIMM1 is the DIMM farthest from the processor on that channel. DIMMs must be populated from farthest slot to closest slot to the processor on a per channel basis (when a daisy chain topology is used). Populations that are not shown in these tables are not supported. These tables document the optimal settings for motherboards which meet the relevant motherboard design guidelines.

- Program D18F2x9C\_x0002\_0087\_dct[3:0][DisAutoComp, DisPredriverCal] = {1,1}.
- Only the value for a single control unit register is described. The values in the tables should be broadcast to all instances of registers of the same control unit type, unless otherwise noted.
- Program D18F2x9C\_x0002\_0087\_dct[3:0][DisAutoComp] = 0.

Table 27: BIOS Recommendations for DDR3 SO-DIMM data bus configuration

### 2.9.9.2.6 Phy FIFO Configuration

BIOS programs FIFO configuration values based on NCLK, memory clock, CASL, and CWL. A read pointer initial value is specified for each NbPstate as well as one reserved for the PMU during training.

The steps for **Ddr3Mode** are as follows:

- For NbP0 broadcast the value to all timing groups and chips as follows:
  - D18F2x9C\_x00[F,3:0]0 [F,3:0][8,3:0]2E\_dct[3:0][RdPtrInitVal]= Table 29.
  - D18F2x9C\_x00[F,8:0]1\_0[8,3:0]2E\_dct[3:0][RdPtrInitVal] = Table 29.
- For each NbPstate, excluding the “NbPstate PMU” instance and the NbP0 instance, program:
  - Broadcast the value to all timing groups and chips.
  - D18F2x9C\_x00[F,3:0]0 [F,3:0][8,3:0]2E\_dct[3:0][RdPtrInitVal]= Table 30.
  - D18F2x9C\_x00[F,8:0]1\_0[8,3:0]2E\_dct[3:0][RdPtrInitVal] = Table 30.
- D18F2x9C\_x0[3,1:0][F,8:0]1\_0028\_dct[3:0][RxRdPtrOffset] as follows:
  - Broadcast the value to all chips.
  - RxRdPtrOffset = CASL.
- D18F2x9C\_x0[3,1:0][F,8:0]1\_0028\_dct[3:0][TxRdPtrOffset] as follows:
  - Broadcast the value to all chips.
  - TxRdPtrOffset = CWL.

Table 29: BIOS Recommendations for DDR3 FIFO RdPtrInitVal for NbP0

| Condition              | NCLK (MHz) |      |      |      |      |      |      |

2. If exact NCLK rate is not shown, use the information from the column of the next highest shown NCLK.
3. Not all conditions are supported. See product definition for details on supported frequencies.

#### 2.9.9.2.7 Phy Predriver Initialization.

Each DDR IO driver has a programmable slew rate controlled by the pre-driver calibration code. The recommended slew rate is a function of the DC drive strength. BIOS initializes the recommended nominal slew rate

values as follows:

1. Program `D18F2x9C_x0002_0087_dct[3:0][DisAutoComp, DisPredriverCal] = {1,1}`.
2. Program `D18F2x9C_x00[F,8:0]1_[F,B:0]05F_dct[3:0][TxPreN, TxPreP]` according to [Table 31](#)
  - For each pad, read `D18F2x9C_x0[3,1:0][F,8:0]1_[F,B:0]041_dct[3:0][DrvStrenP]` and program the corresponding pad in `D18F2x9C_x00[F,8:0]1_[F,B:0]05F_dct[3:0]`.
  - Use DrvStrenP for memory P-state 0 to determine slew rate.
  - If the chosen DrvStrenP value is not listed in the table for the given DDR rates, then use the next lower DrvStrenP value listed to determine TxPreN and TxPreP.
3. Program `D18F2x9C_x00[F,3:0]0_[F,B:0]05F_dct[3:0][TxPreN, TxPreP]` for Cmd/Addr according to [Table 32](#).
  - For each Cmd/Addr pad (MEMCKE[3:0], MEMADD[15:0], MEMBANK[2:0], MEMCS\_L[7:0], MEMODT[3:0], MEMCAS\_L, MEMWE\_L, MEMRAS\_L):
    - Read `D18F2x9C_x0[3,1:0][F,3:0]0_[F,B:0]041_dct[3:0][DrvStrenP]` and program the corresponding pad in `D18F2x9C_x00[F,3:0]0_[F,B:0]05F_dct[3:0][TxPreN, TxPreP]`.
  - Use DrvStrenP for memory P-state 0 to determine slew rate.
  - If the chosen DrvStrenP value is not listed in the table for the given DDR rates, then use the next lower DrvStrenP value listed to determine TxPreN and TxPreP.
4. Program `D18F2x9C_x00[F,3:0]0_[F,B:0]05F_dct[3:0][TxPreN, TxPreP]` for clocks according to [Table 33](#).
  - For each clock pad (MEMCLK\_H[4:0], MEMCLK\_L[4:0]):
    - Read `D18F2x9C_x0[3,1:0][F,3:0]0_[F,B:0]041_dct[3:0][DrvStrenP]` and program the corresponding pad in `D18F2x9C_x00[F,3:0]0_[F,B:0]05F_dct[3:0][TxPreN, TxPreP]`.
  - Use DrvStrenP for memory P-state 0 to determine slew rate.
  - If the chosen DrvStrenP value is not listed in the table for the given DDR rates, then use the next lower DrvStrenP value listed to determine TxPreN and TxPreP.
5. Program `D18F2x9C_x0002_0087_dct[3:0][DisAutoComp, DisPredriverCal] = {0,0}`.

**Table 31: Phy predriver codes for Data/DQS**

| DDR Rate                                                             | DrvStrenP <sup>1</sup> | {TxPreN, TxPreP} <sup>2</sup><br>VDDIO=1.5V | {TxPreN, TxPreP} <sup>2</sup><br>VDDIO=1.35V | {TxPreN, TxPreP} <sup>2</sup><br>VDDIO=1.25V |
|----------------------------------------------------------------------|------------------------|---------------------------------------------|----------------------------------------------|----------------------------------------------|
| 667 - 1067                                                           | 31h                    | 101b,111b                                   | 101b,111b                                    | 101b,111b                                    |

### 2.9.9.2.8 Phy Auto-Calibration

BIOS enables a one-time calibration after configuration dependent values are programmed as follows:

1. Initiate one-time calibration. See 2.9.9.2.8.1.
2. After the PMU firmware is loaded, BIOS ensures that the initial calibration is complete prior to executing PMU firmware. See appropriate section for details.
3. After PMU training is complete, or after complete restore of trained values from NVRAM, BIOS initiates auto calibration. See 2.9.9.2.8.3

#### 2.9.9.2.8.1 One-Time Pre-PMU Calibration

BIOS initiates one calibration. On S5 boot BIOS does this before loading PMU firmware.

1. Program `D18F2x9C_x0002_0088_dct[3:0][CalInitMode, CalOnce] = {1,1}`.
2. Program `D18F2x9C_x0002_0088_dct[3:0][CalRun] = 1`.
3. Program `D18F2x9C_x0002_0088_dct[3:0][CalOnce, CalRun] = {0,0}`.

#### 2.9.9.2.8.2 Fence CalOnce

BIOS ensures the initial one-time calibration is complete as follows:

1. Read `D18F2x9C_x0002_0097_dct[3:0][CalBusy]`. This read value is thrown away.
2. Read `D18F2x9C_x0002_0097_dct[3:0][CalBusy]` until `CalBusy = 0`.

#### 2.9.9.2.8.3 Auto Calibration

BIOS initiates auto calibration after PMU training or after complete restore of trained values from NVRAM.

1. Program `D18F2x9C_x0002_0088_dct[3:0][CalInitMode] = 0`.
2. Program `D18F2x9C_x0002_0088_dct[3:0][CalRun] = 1`.

### 2.9.9.2.9 PMU Firmware Load

BIOS loads the PMU firmware (see 2.9.8 [PMU]) after each system reset before requesting the PMU to take action with down-stream messages.

Firmware block LENGTH = 16\*1024.

1. Program `D18F2x9C_x0002_0099_dct[3:0][PmuReset] = 0` for each phy.
2. Program `D18F1x10C[DctCfgBcEn] = 1`.
3. For each 16-bit word of the firmware block: Write the word to `D18F2x[B,0]9C_x0005_[5BFF:4000]_dct[3:0]` (while using the autoincrement feature).
4. Program `D18F1x10C[DctCfgBcEn] = 0`.

Additionally, there is a sequence of register writes provided by AMD to write compiler/tool specific data into the data SRAM for use in the PMU executive.

### 2.9.9.2.10 Phy Registers Required for S3 Resume

To support suspend-to-RAM, BIOS must save registers to NVRAM prior to S3 entry, and restore them when resuming. The following is not a complete list. See 2.9.9 [DCT/DRAM Initialization and Resume] for information on other registers. BIOS restores the following registers, which have been trained by the PMU during boot:

- D18F2x9C\_x0[3,1:0][F,3:0]0\_F[3:0]028\_dct[3:0]
- D18F2x9C\_x0[3,1:0][F,8:0]1\_0028\_dct[3:0]
- D18F2x9C\_x0[3,1:0][F,3:0]0\_F[3:0]081\_dct[3:0]
- D18F2x9C\_x0[F,1:0][F,8:0]1\_F[9:0][F,3:0]80\_dct[3:0]
- D18F2x9C\_x0[F,1:0][F,8:0]1\_F[9:0][F,3:0]81\_dct[3:0]
- D18F2x9C\_x0[3,1:0][F,8:0]1\_F[B:0]046\_dct[3:0]
- D18F2x9C\_x0[3,1:0][F,8:0]1\_F[B:0]047\_dct[3:0]
- D18F2x9C\_x0[3,1:0][F,8:0]1\_F[B:0]048\_dct[3:0]

### 2.9.9.2.11 Calculating Round Trip Command Delays

Software calculates trained round trip delays as follows.

MaxRxCmdDelay, maximum command to data read delay, in units of 2 UI:

- Compute worst case for each chip and when available for each DQ pad within a chip.
- $\text{MaxRxCmdDelay} = \text{MAX}(\text{D18F2x9C\_x0[3,1:0][F,8:0]1\_0028\_dct[3:0][RxRdPtrOffset]} + \text{CEIL}(\text{D18F2x9C\_x0[F,1:0][F,8:0]1\_F[9:0][F,3:0]80\_dct[3:0][RxDly]/64))$

### 2.9.9.3 SPD ROM-Based Configuration

The Serial Presence Detect (SPD) ROM is a non-volatile memory device on the DIMM encoded by the DIMM manufacturer. The description of the SPD is usually provided on a data sheet for the DIMM itself along with data describing the memory devices used. The data describes configuration and speed characteristics of the DIMM and the SDRAM components mounted on the DIMM. The associated data sheet also contains the DIMM byte values that are encoded in the SPD on the DIMM.

BIOS reads the values encoded in the SPD ROM through a system-specific interface. BIOS acquires DIMM configuration information, such as the amount of memory on each DIMM, from the SPD ROM on each DIMM and uses this information to program the DRAM controller registers.

For solder-down DRAM, in the absence of an SPD ROM, BIOS provides the information necessary for DRAM configuration.

The SPD ROM provides values for several DRAM timing parameters that are required by the DCT. In general, BIOS should use the optimal value specified by the SPD ROM.

For [Ddr3Mode](#), these parameters are:

- D18F2x84\_dct[3:0][Twr]: Write recovery time
- D18F2x8C\_dct[3:0][Tref]
- D18F2x200\_dct[3:0]\_mp[1:0][Tras]: Active to precharge time
- D18F2x200\_dct[3:0]\_mp[1:0][Trp]: Precharge time
- D18F2x200\_dct[3:0]\_mp[1:0][Tred]: RAS to CAS delay
- D18F2x200\_dct[3:0]\_mp[1:0][Tcl]: CAS latency
- D18F2x204\_dct[3:0]\_mp[1:0][Trtp]: Internal read to precharge command delay time

- [D18F2x204\\_dct\[3:0\]\\_mp\[1:0\]\[FourActWindow\]](#): Four activate window delay time
- [D18F2x204\\_dct\[3:0\]\\_mp\[1:0\]\[Trrd\]](#): Row active to row active delay
- [D18F2x204\\_dct\[3:0\]\\_mp\[1:0\]\[Trc\]](#): Active to active/refresh time
- [D18F2x208\\_dct\[3:0\]\[Trfc3, Trfc2, Trfc1, Trfc0\]](#): Refresh recovery delay time
- [D18F2x20C\\_dct\[3:0\]\\_mp\[1:0\]\[Twtr\]](#): Internal write to read command delay time

Optimal cycle time is specified for each DIMM and is used to limit or determine bus frequency. See [2.9.9.5 \[DRAM Device Initialization and Training\]](#).

### 2.9.9.3.1 DRAM ODT Pin Control

This section applies to [Ddr3Mode](#) only.

BIOS configures the DIMM ODT behavior per chip select according to the DIMM population. In all cases, the processor ODT is off for writes and is on for reads. The ODT pin patterns for reads and writes are programmed using [D18F2x\[234:230\]\\_dct\[3:0\]](#) and [D18F2x\[23C:238\]\\_dct\[3:0\]](#), respectively.

**Table 34: DDR3 DIMM ODT Pattern**

| DIMM0 <sup>1</sup>                                                                                                                                                                      | DIMM1 <sup>1</sup>    | <a href="#">D18F2x[234:230]_dct[3:0]</a> |            | <a href="#">D18F2x[23C:238]_dct[3:0]</a> |            |

### 2.9.9.4 DCT Specific Configuration

The DCT requires certain features be disabled during DRAM device initialization and training. BIOS should program the registers in [Table 35](#) before DRAM device initialization and training. For normal operation, BIOS programs the recommended values if provided in [Table 35](#). BIOS must quiesce all other forms of DRAM traffic on the channel being trained. See [2.9.9 \[DCT/DRAM Initialization and Resume\]](#).

**Table 35: DCT Training Specific Register Values**

| Register                                                        | Mode                     | Training | Normal Operation              |
|-----------------------------------------------------------------|--------------------------|----------|-------------------------------|

#### 2.9.9.4.1 DDR3 Turnaround Parameters

This section and all of the following sub-sections apply to [Ddr3Mode](#) only.

- LD (latency difference) = D18F2x200\_dct[3:0]\_mp[1:0][Tcl] - D18F2x20C\_dct[3:0]\_mp[1:0][Tewl].
- WOD (Write ODT Delay) = MAX(0, D18F2x240\_dct[3:0]\_mp[1:0][WrOdtOnDuration] - 6).

In all cases, if the computed turn around time is less than the smallest non-reserved value in the register then software programs the smallest non-reserved value.

##### 2.9.9.4.1.1 TrdrdBan, TrdrdSdSc, TrdrdSdDc, and TrdrdDd (Rd->Rd Timing)

This section applies to [Ddr3Mode](#) only.

The optimal values for D18F2x218\_dct[3:0]\_mp[1:0][TrdrdBan, TrdrdSdSc, TrdrdSdDc, TrdrdDd] are platform and configuration specific and should be characterized for best performance. After DRAM training, BIOS should use the guidelines below to configure the recommended platform generic timing values:

- CD\_R\_R, CD\_R\_R\_SD, and Trdrdban\_Phy are obtained from the PMU via the [SRAMMsgBlk](#).
- TrdrdSdSc = 1.
- TrdrdSdDc = CD\_R\_R\_SD.
- TrdrdDd = CD\_R\_R.
- TrdrdBan = Trdrdban\_Phy.

##### 2.9.9.4.1.2 TwrwrSdSc, TwrwrSdDc, TwrwrDd (Wr->Wr Timing)

This section applies to [Ddr3Mode](#) only.

The optimal values for [D18F2x214\\_dct\[3:0\]\\_mp\[1:0\]](#)[TwrrwSdSc, TwrrwSdDc, TwrrwDd] are platform and configuration specific and should be characterized for best performance. After DRAM training, BIOS should use the guidelines below to configure the recommended platform generic timing values:

- CD\_W\_W and CD\_W\_W\_SD are obtained from the PMU via the [SRAMMsgBlk](#).
- TwrrwSdSc = 1.
- TwrrwSdDc = CD\_W\_W\_SD.
- TwrrwDd = CD\_W\_W.

#### 2.9.9.4.1.3 Twrrd (Write to Read DIMM Termination Turn-around)

This section applies to [Ddr3Mode](#) only.

The optimal value for [D18F2x218\\_dct\[3:0\]\\_mp\[1:0\]](#)[Twrrd] is platform and configuration specific and should be characterized for best performance. Prior to DRAM training, BIOS should program this parameter to the largest defined value. After DRAM training, BIOS should use the guidelines below to configure the recommended platform generic timing values:

- Twrrd = CD\_W\_R obtained from the PMU via the [SRAMMsgBlk](#).

#### 2.9.9.4.1.4 TrwtTO (Read-to-Write Turnaround for Data, DQS Contention)

This section applies to [Ddr3Mode](#) only.

The optimal value for [D18F2x21C\\_dct\[3:0\]\\_mp\[1:0\]](#)[TrwtTO] is platform and configuration specific and should be characterized for best performance. Prior to DRAM training, BIOS should program this parameter to the largest defined value. After DRAM training, BIOS should use the guidelines below to configure the recommended platform generic timing values after DDR training is complete:

- TrwtTO = CD\_R\_W obtained from the PMU via the [SRAMMsgBlk](#).

### 2.9.9.5 DRAM Device Initialization and Training

BIOS requests the PMU to initialize the bus and devices, as well as train the processor for optimal operation, using the SequenceCtl bitmap in [SRAMMsgBlk](#), and by taking the PMU out of reset to execute the requests.

In the following steps, BIOS performs each step for each DCT={[MaxDctMstr:0](#)}, keeping the PMUs in lock-step, before moving to the next step.

1. Perform the PMU firmware load for the module containing Devinit. See [2.9.9.2.9](#).
2. Program [SRAMMsgBlk](#) with all values necessary for Devinit. See [2.9.8.3](#).
3. Set [SRAMMsgBlk](#), field SequenceCtl = 0x7F for a single module solution, or set [SRAMMsgBlk](#), field SequenceCtl = 0x1F for a two module solution (see below).
4. Fence the CalOnce. See [2.9.9.2.8.2](#).
5. Program [D18F2x9C\\_x0002\\_0099\\_dct\[3:0\]](#)[PmuStall] = 0.
6. mboxUSPend(PMUQEmpty). See [2.9.8.1](#).
  - If message is FAIL then continue to step 7 for that DCT only; In keeping with the requirement above, begin next step only after all DCTs are ready.

7. Read [SRAMMsgBlk](#) and store for later use.

If the total firmware size makes it necessary to load and execute two firmware modules consecutively for complete boot then BIOS performs the following additional steps. BIOS performs each step for each DCT={[MaxDctMstr:0](#)}, keeping the PMUs in lockstep, before moving to the next step.

1. Program [D18F2x9C\\_x0002\\_0099\\_dct\[3:0\]\[PmuReset,PmuStall\]](#) = 1,1.
2. Program [D18F2x9C\\_x0002\\_0099\\_dct\[3:0\]\[PmuReset\]](#) = 0.
3. Perform the PMU firmware load for the module containing 2D Read Training. See [2.9.9.2.9](#).
  - [SRAMMsgBlk](#) values from first PMU execution should be preserved. Do not overwrite [SRAMMsgBlk](#).
4. Program [SRAMMsgBlk](#) with all values necessary for 2D Read Training. See [2.9.8.3](#).
5. Set [SRAMMsgBlk](#), field [SequenceCtl](#) = 0x60.
6. Program [D18F2x9C\\_x0002\\_0099\\_dct\[3:0\]\[PmuStall\]](#) = 0.
7. [mboxUSPend\(PMUQEmpty\)](#). See [2.9.8.1](#).

### 2.9.9.6 DRAM Training

The PMU trains the I/O timing and electrical parameters on the DDR bus. BIOS initiates the training using a command bitmap in the [SRAMMsgBlk](#) of each PMU, keeping each PMU in lockstep. See [2.9.9.5](#).

Once the I/O timing is trained, the BIOS trains the round trip data latency path from the controller through the channel and back to the northbridge. See [2.9.9.6.1](#).

#### 2.9.9.6.1 Training MaxRdLatency

After DRAM training, BIOS optimizes [D18F2x210\\_dct\[3:0\]\\_nbp\[3:0\]\[MaxRdLatency\]](#) using the following algorithm. For MaxRdLatency training, BIOS generates a training pattern using continuous read or write data streams. See [2.9.10.1 \[DCT Training Pattern Generation\]](#).

For each DCT={[MaxDct:0](#)}:

1. Calculate a starting MaxRdLatency delay value by converting [Tcl](#) to NCLKs. See [D18F2x200\\_dct\[3:0\]\\_mp\[1:0\]\[Tcl\]](#).
2. Select 32 64-byte aligned test addresses associated with the chipselect that has the worst case round trip delay ([D18F2x9C\\_x0\[F,1:0\]\[F,8:0\]1\\_\[F,9:0\]\[F,3:0\]80\\_dct\[3:0\]\[RxDly\]](#) (for a DQ pad) + [D18F2x9C\\_x0\[F,1:0\]\[F,8:0\]1\\_\[F,9:0\]\[F,3:0\]80\\_dct\[3:0\]\[RxDly\]](#) (for a DQS pad within the same bytelane as the DQ pad).
3. Write the DIMM test addresses with the training pattern.
4. For each MaxRdLatency value incrementing from the value calculated in step 1:
  - A. Program [D18F2x210\\_dct\[3:0\]\\_nbp\[3:0\]\[MaxRdLatency\]](#) with the current value.
  - B. Read the DIMM test addresses.
  - C. Compare the values read against the pattern written.
    - If the pattern is read correctly, go to step 5.
5. Program [D18F2x210\\_dct\[3:0\]\\_nbp\[3:0\]\[MaxRdLatency\]](#) = CEIL(current value + fudge factor).
  - NB P-state 0 fudge factor = 1 NCLK + 3 MEMCLK
  - NB P-state [3:1] fudge factor = 3 NCLK + 3 MEMCLK

### 2.9.9.7 Synchronous Channel Initialization

- BIOS ensures that the frequency is programmed in the DCT correctly prior to the channel initialization. See [D18F2x94\\_dct\[3:0\]\[MemClkFreq\]](#), [D18F2x2E0\\_dct\[3:0\]\[M1MemClkFreq\]](#).

- IF (Ddr3Mode) then BIOS programs DCT specific read pointer initial values as specified in step 2 of 2.9.9.2.6 [Phy FIFO Configuration] prior to the channel initialization.

1. IF resuming from an S3 system state and the DRAMs are in self-refresh, then
  - Program D18F2x9C\_x00FF\_000D\_dct[3:0][PhyClkCtl]= 1.
2. Program D18F2x78\_dct[3:0][PtrInitReq]=1. Wait for D18F2x78\_dct[3:0][PtrInitReq]==0.

### 2.9.9.8 DRAM Channel Disable

The following steps are performed to disable an unused DRAM channel:

1. Program D18F2x9C\_x03FF\_F041\_dct[3:0]=0000\_0000h.
  - See D18F2x9C\_x0[3,1:0][F,3:0]0\_[F,B:0]041\_dct[3:0], and D18F2x9C\_x0[3,1:0][F,8:0]1\_[F,B:0]041\_dct[3:0].
2. Program D18F2x9C\_x00FA\_F04A\_dct[] = 0080h.
  - See D18F2x9C\_x00[F,3:0]0\_[F,B:0]04A\_dct[3:0] and D18F2x9C\_x0009\_004A\_dct[3:0].
3. Program D18F2x9C\_x0002\_000B\_dct[3:0] = 0000\_0004h.
4. Ensure that D18F2x78\_dct[3:0][ChanVal] = 0.
5. Ensure that D18F2x90\_dct[3:0][DisDllShutdownSR] = 1.
6. Program D18F2x94\_dct[3:0][DisDramInterface] = 1.

If a DCT does not exist then these steps must be skipped.

### 2.9.9.9 DRAM Phy Power Savings

For power savings, BIOS should perform the following actions for each enabled channel:

1. Program D18F2x9C\_x0[3,1:0][F,3:0]0\_[F,B:0]041\_dct[3:0] as follows to disable unused pads.
  - DrvStrenN = DrvStrenP = 0.
  - See 2.9.4. Software does this for each unconnected pad in the package or each pad connected to unused pin(s).
2. Program D18F2x9C\_x0[3,1:0][F,3:0]0\_0014\_dct[3:0][MaxDurDllNoLock] = 0.
3. Program D18F2x9C\_x0[3,1:0][F,8:0]1\_0014\_dct[3:0][MaxDurDllNoLock,DllPumpPeriod] as follows:
  - If (DDR rate <= 1067) MaxDurDllNoLock = 9h
  - else MaxDurDllNoLock = 7h
  - DllPumpPeriod = 3h
4. Program D18F2x9C\_x0[3,1:0][F,8:0]1\_[F,B:0]04D\_dct[3:0] as follows:
  - For M1 context program ODTStrenN = ODTStrenP = 0.
5. Program D18F2x9C\_x01F1\_F043\_dct[3:0] = 0004h.
  - See D18F2x9C\_x0[3,1:0][F,8:0]1\_[F,7:0]043\_dct[3:0].
6. Program D18F2x9C\_x00FA\_F04A\_dct[] = 0080h.
  - See D18F2x9C\_x00[F,3:0]0\_[F,B:0]04A\_dct[3:0] and D18F2x9C\_x0009\_004A\_dct[3:0].
7. Power down unused DBYTE 9 (undocumented spare) as follows:
  - Program D18F2x9C\_x0091\_F04A\_dct[] = 0280h.
  - Program D18F2x9C\_x0091\_0F77\_dct[] = 07CFh.
  - Program D18F2x9C\_x0091\_0000\_dct[] = 00004.
  - Program D18F2x9C\_x0091\_0F77\_dct[] = 07DFh.
  - Program D18F2x9C\_x0391\_F04D\_dct[] = 0000h.

- Program D18F2x9C\_x0391\_F041\_dct[] = 0000h.
8. Disable unused DLL components in ABYTE as follows:
    - Program D18F2x9C\_x0020\_0077\_dct[] = 07C0h.
    - Program D18F2x9C\_x0030\_0077\_dct[] = 07C0h.
    - Program D18F2x9C\_x0000\_0077\_dct[] = 07C4h.
    - Program D18F2x9C\_x0010\_0077\_dct[] = 07C4h.
    - See [D18F2x9C\\_x00\[F,3:0\]0\\_0077\\_dct\[3:0\]](#)
  9. If ECC memory is not connected or is disabled, or the package does not support ECC, then power down data chiplet 8 with the following:
    - Write to all memory P-state instances if available.
    - Program [D18F2x9C\\_x00\[F,8:0\]1\\_\[F,B:0\]04A\\_dct\[3:0\]](#) = 0280h.
    - Program [D18F2x9C\\_x00\[F,8:0\]1\\_0\[F,2:0\]77\\_dct\[3:0\]](#) = 07CFh.
    - Program [D18F2x9C\\_x00\[F,8:0\]1\\_0000\\_dct\[3:0\]](#) = 00004.
    - Program [D18F2x9C\\_x00\[F,8:0\]1\\_0\[F,2:0\]77\\_dct\[3:0\]](#) = 07DFh.
    - Program [D18F2x9C\\_x0\[3,1:0\]\[F,8:0\]1\\_\[F,B:0\]04D\\_dct\[3:0\]](#) = 0000h.
    - Program [D18F2x9C\\_x0\[3,1:0\]\[F,8:0\]1\\_\[F,B:0\]041\\_dct\[3:0\]](#) = 0000h.
  10. Power down unused receivers in data chips as follows:
    - Program D18F2x9C\_x00F1\_804A\_dct[] = 280h.
    - Program D18F2x9C\_x00F1\_904A\_dct[] = 280h.
    - If x4 DIMMs are not present then program D18F2x9C\_x00F1\_B04A\_dct[] = 280h.
    - See [D18F2x9C\\_x00\[F,8:0\]1\\_\[F,B:0\]04A\\_dct\[3:0\]](#)
  11. Power down the PMU as follows:
    - Program [D18F2x9C\\_x0002\\_0099\\_dct\[3:0\]\[PmuReset,PmuStall\]](#) = {1,1}.
    - Program [D18F2x9C\\_x0002\\_0099\\_dct\[3:0\]\[SRAM\\_SD\]](#) = 1.
    - For M0 context program [D18F2x9C\\_x0\[1:0\]02\\_0080\\_dct\[3:0\]\[PMUClkDiv\]](#) = 7.

## 2.9.10 Continuous Pattern Generation

DRAM training relies on the ability to generate a string of continuous reads or writes between the processor and DRAM, such that worst case electrical interactions can be created. This section describes how these continuous strings of accesses may be generated.

### 2.9.10.1 DCT Training Pattern Generation

DCT training pattern generation uses pattern generators in the DCT to generate controlled read and write traffic streams. During write pattern generation, data values based off of a deterministic pattern are burst to the DRAM interface. Conversely for reads, data bursts from the DRAM interface are compared against expected data values on a per nibble basis.

Two address modes are available for DRAM training pattern generation, as configured by [D18F2x250\\_dct\[3:0\]\[CmdTgt\]](#). For generating a stream of reads or writes to the same rank, address target A mode is used. To generate a stream of accesses to up to two different ranks, address target A and B mode is used.

An overview of the BIOS sequence to generate training patterns is as follows:

- Configure the DCT for pattern generation. See [2.9.9.4 \[DCT Specific Configuration\]](#).
- Ensure DIMMs are configured to support 8-beat bursts (BL8 or dynamic burst length on the fly).
- Wait for [D18F2x250\\_dct\[3:0\]\[CmdSendInProg\]](#) = 0.
- Program [D18F2x250\\_dct\[3:0\]\[CmdTestEnable\]](#) = 1.
- Send activate commands as appropriate. See [2.9.10.1.1 \[Activate and Precharge Command Generation\]](#).
- Send read or write commands as desired. See [2.9.10.1.2 \[Read and Write Command Generation\]](#).
- Send precharge commands as appropriate. See [2.9.10.1.1 \[Activate and Precharge Command Generation\]](#).
- Program [D18F2x250\\_dct\[3:0\]\[CmdTestEnable\]](#) = 0.

#### 2.9.10.1.1 Activate and Precharge Command Generation

Prior to sending read or write commands, BIOS must send an activate command to a row in a particular bank of the DRAM devices for access. To send an activate command, BIOS performs the following steps:

- Program [D18F2x28C\\_dct\[3:0\]](#) to the desired address as follows:
  - [CmdChipSelect](#) = [CS\[7:0\]](#).
  - [CmdBank](#) = [BA\[2:0\]](#).
  - [CmdAddress](#) = [A\[17:0\]](#).
- Program [D18F2x28C\\_dct\[3:0\]\[SendActCmd\]](#) = 1.
- Wait until [D18F2x28C\\_dct\[3:0\]\[SendActCmd\]](#) = 0.
- Wait 75 MEMCLKs.

After completing its accesses, BIOS must deactivate open rows in the DRAM devices. To send a precharge or precharge all command to deactivate open rows in a bank or in all banks, BIOS performs the following steps:

- Wait 25 MEMCLKs.
- Program [D18F2x28C\\_dct\[3:0\]](#) to the desired address as follows:
  - [CmdChipSelect](#) = [CS\[7:0\]](#).
  - Precharge all command:
    - [CmdAddress\[10\]](#) = 1.
  - Precharge command:
    - [CmdAddress\[10\]](#) = 0.
    - [CmdBank](#) = [BA\[2:0\]](#).

- Program `D18F2x28C_dct[3:0][SendPchgCmd]` = 1.
- Wait until `D18F2x28C_dct[3:0][SendPchgCmd]` = 0.
- Wait 25 MEMCLKs.

### 2.9.10.1.2 Read and Write Command Generation

BIOS performs the following steps for read pattern generation:

- Program `D18F2x27C_dct[3:0]`, `D18F2x278_dct[3:0]`, and `D18F2x274_dct[3:0]` with the data comparison masks for bit lanes of interest.
- Program `D18F2x270_dct[3:0][DataPrbsSeed]` the seed for the desired PRBS.
- Program `D18F2x260_dct[3:0][CmdCount]` equal to the number of cache line commands.
- Program `D18F2x25C_dct[3:0][BubbleCnt, CmdStreamLen]`. See 2.9.10.1.4 [BubbleCnt and CmdStreamLen Programming].
- Program `D18F2x25[8,4]_dct[3:0]` to the initial address.
- Program `D18F2x250_dct[3:0]` as follows:
  - ResetAllErr and StopOnErr as desired. See 2.9.10.1.3 [Data Comparison].
  - CmdTgt corresponding to `D18F2x25[8,4]_dct[3:0]`.
  - CmdType = 000b.
  - SendCmd = 1.
- If `D18F2x260_dct[3:0][CmdCount] != 0` then
  - Wait for `D18F2x250_dct[3:0][TestStatus] = 1` and `D18F2x250_dct[3:0][CmdSendInProg] = 0`.
  - Else
    - Wait the desired amount of time.
    - Program `D18F2x260_dct[3:0][CmdCount] = 1`.
    - Wait for `D18F2x250_dct[3:0][TestStatus] = 1` and `D18F2x250_dct[3:0][CmdSendInProg] = 0`.
- Program `D18F2x250_dct[3:0][SendCmd] = 0`.
- Read `D18F2x264_dct[3:0]`, `D18F2x268_dct[3:0]`, and `D18F2x26C_dct[3:0]` if applicable.

BIOS performs the following steps for write pattern generation:

- Program `D18F2x270_dct[3:0][DataPrbsSeed]` the seed for the desired PRBS.
- Program `D18F2x260_dct[3:0][CmdCount]` equal to the number of cache line commands desired.
- Program `D18F2x25C_dct[3:0][BubbleCnt, CmdStreamLen]`. See 2.9.10.1.4 [BubbleCnt and CmdStreamLen Programming].
- Program `D18F2x25[8,4]_dct[3:0]` to the initial address.
- Program `D18F2x250_dct[3:0]` as follows:
  - CmdTgt corresponding to `D18F2x25[8,4]_dct[3:0]`.
  - CmdType = 001b.
  - SendCmd = 1.
- If `D18F2x260_dct[3:0][CmdCount] != 0` then
  - Wait for `D18F2x250_dct[3:0][TestStatus] = 1` and `D18F2x250_dct[3:0][CmdSendInProg] = 0`.
  - Else
    - Wait the desired amount of time.
    - Program `D18F2x260_dct[3:0][CmdCount] = 1`.
    - Wait for `D18F2x250_dct[3:0][TestStatus] = 1` and `D18F2x250_dct[3:0][CmdSendInProg] = 0`.
- Program `D18F2x250_dct[3:0][SendCmd] = 0`.

BIOS combines the two sets of steps listed above for alternating write and read pattern generation.

### 2.9.10.1.3 Data Comparison

The DCT compares the incoming read data against the expected pattern sequence during pattern generation. BIOS may choose to continue command generation and accumulate errors or stop command generation on the first error occurrence by programming [D18F2x250\\_dct\[3:0\]\[StopOnErr\]](#).

Error information is reported via [D18F2x264\\_dct\[3:0\]](#), [D18F2x268\\_dct\[3:0\]](#), [D18F2x26C\\_dct\[3:0\]](#), [D18F2x294\\_dct\[3:0\]](#), [D18F2x298\\_dct\[3:0\]](#) and [D18F2x29C\\_dct\[3:0\]](#). Error information can be masked on per-bit basis by programming [D18F2x274\\_dct\[3:0\]](#), [D18F2x278\\_dct\[3:0\]](#), and [D18F2x27C\\_dct\[3:0\]](#).

BIOS resets the error information by programming [D18F2x250\\_dct\[3:0\]\[ResetAllErr\]](#)=1.

Error information is only valid in certain modes of [D18F2x250\\_dct\[3:0\]\[CmdType, CmdTgt\]](#) and [D18F2x260\\_dct\[3:0\]\[CmdCount\]](#) and when using 64 byte aligned addresses in [D18F2x25\[8,4\]\\_dct\[3:0\]\[TgtAddress\]](#). Some modes require a series of writes to setup a DRAM data pattern. See [Table 36](#).

**Table 36. Command Generation and Data Comparison**

| Commands   | CmdType | Cmd Tgt          | Maximum CmdCount <sup>4</sup> |
|------------|---------|------------------|-------------------------------|
| Read       | 000b    | 00b <sup>1</sup> | 128                           |
|            |         | 01b <sup>1</sup> | 256 <sup>2</sup>              |
| Write-Read | 010b    | 00b              | Infinite                      |
|            |         | 01b <sup>3</sup> | 256 <sup>2</sup>              |

1. Requires setup writes to store a data pattern in DRAM. The write commands are generated using the same CmdTgt, CmdCount, and DataPrbsSeed settings.
2. D18F2x254[TgtAddress] != D18F2x258[TgtAddress].
3. Requires setup writes to store a data pattern in DRAM. The write commands are generated programming D18F2x254[TgtAddress] to the intended Target B, CmdTgt=00b, CmdCount to 1/2 of the intended command count, and the same DataPrbsSeed setting.
4. D18F2x250\_dct[3:0][LsfrRollOver]=0. The maximum CmdCount is infinite for all modes listed if D18F2x250\_dct[3:0][LsfrRollOver]=1.

### 2.9.10.1.4 BubbleCnt and CmdStreamLen Programming

BIOS programs [D18F2x25C\\_dct\[3:0\]\[BubbleCnt2, BubbleCnt, CmdStreamLen\]](#) to ensure proper channel command spacing in command generation mode.

For continuous pattern generation it is expected that BubbleCnt = 0. In other modes, BIOS programs BubbleCnt, BubbleCnt2, and CmdStreamLen greater than or equal to the relevant DRAM timing parameters shown below to prevent contention on the DRAM bus. In all cases, if the minimum BubbleCnt > 0 or CmdType = 010b then BIOS programs CmdStreamLen = 1.

**Table 37. DDR3 Command Generation and BubbleCnt Programming**

| Commands                   | CmdType | CmdTgt | BubbleCnt                                                                                                  | BubbleCnt2                             |
|----------------------------|---------|--------|------------------------------------------------------------------------------------------------------------|----------------------------------------|

### 2.9.11 Memory Interleaving Modes

The processor supports the following memory interleaving modes:

- Chip select: interleaves the physical address space over multiple DIMM ranks on a channel, as opposed to each DIMM owning single consecutive address spaces. See 2.9.11.1 [Chip Select Interleaving].
- Channel: interleaves the physical address space over multiple channels, as opposed to each channel owning single consecutive address spaces. See 2.9.11.2 [Channel Interleaving].

Any combination of these interleaving modes may be enabled concurrently.

**Table 38. Recommended Interleave Configurations**

| Interleaving Mode                                                        | Enabled                                                                                                              | Disabled                                                                                                         |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Chip Select Interleaving                                                 | Number of chip selects installed on the channel is a power of two.                                                   | Requirements not satisfied.                                                                                      |
| Channel Interleaving                                                     | DIMMs are present on a power of two number of channels.                                                              | Requirements not satisfied.                                                                                      |
| Interleave Region Remapping <sup>1</sup>                                 | UMA and DIMMs are present on a power of two number of channels and the channels do not have the same amount of DRAM. | ~UMA or all channels have the same amount of DRAM or DIMMs are not present on a power of two number of channels. |
| 1. The channel interleave region should always include the frame buffer. |                                                                                                                      |                                                                                                                  |

**2.9.11.1 Chip Select Interleaving**

The chip select memory interleaving mode has the following requirements:

- The number of chip selects interleaved is a power of two.
- The chip selects are the same size and type.

A BIOS algorithm for programming [D18F2x\[5C:40\]\\_dct\[3:0\] \[DRAM CS Base Address\]](#) and [D18F2x\[6C:60\]\\_dct\[3:0\] \[DRAM CS Mask\]](#) in memory interleaving mode is as follows:

- 1.Program all DRAM CS Base Address and DRAM CS Mask registers using contiguous normalized address mapping.
- 2.For each enabled chip select, swap the corresponding BaseAddr[38:27] bits with the BaseAddr[21:11] bits as defined in [Table 39](#).
- 3.For each enabled chip select, swap the corresponding AddrMask[38:27] bits with the AddrMask[21:11] bits as defined in [Table 39](#).

**Table 39. DDR3 Swapped Normalized Address Lines for CS Interleaving**

| DIMM Address Map <sup>1</sup> | Chip Select Size | (BankSwap, BankSwapLoAddress) <sup>2</sup> | Swapped Base Address and Address Mask bits |                       |
|-------------------------------|------------------|--------------------------------------------|--------------------------------------------|-----------------------|
|                               |                  |                                            | 4 way CS interleaving                      | 2 way CS interleaving |

| <ol style="list-style-type: none"> <li>See <a href="#">D18F2x80_dct[3:0]</a> [DRAM Bank Address Mapping].</li> <li>See <a href="#">D18F2xA8_dct[3:0]</a>[BankSwap] and <a href="#">D18F2x110</a>[BankSwapAddr8En, DctSelIntLvAddr]. If BankSwapAddr8En==1 &amp;&amp; DctSelIntLvAddr==100b then BankSwapLoAddress=8 ELSE BankSwapLoAddress=9.</li> </ol> |                   |                                            |                                            |                       |

The following is an example of interleaving a 64-bit interface to DDR3 DRAM. The DRAM memory consists of two 512 MB dual rank DDR3 DIMMs.

- The register settings for contiguous memory mapping are:
  - [D18F2x80\\_dct\[3:0\]](#) = 0000\_0011h. // CS0/1 = 256 MB; CS2/3 = 256 MB
  - [D18F2x40](#) = 0000\_0001h. // 0 MB base
  - [D18F2x44](#) = 0010\_0001h. // 256 MB base = 0 MB + 256 MB
  - [D18F2x48](#) = 0020\_0001h. // 512 MB base = 256 MB + 256 MB
  - [D18F2x4C](#) = 0030\_0001h. // 768 MB base = 512 MB + 256 MB
  - [D18F2x60](#) = 0008\_FFE0h. // CS0/CS1 = 256 MB
  - [D18F2x64](#) = 0008\_FFE0h. // CS2/CS3 = 256 MB
- The base address bits to be swapped are defined in [Table 39](#), 256MB chip select size, 4 way CS interleaving column. The BaseAddr[29:28] bits are specified by [D18F2x\[5C:40\]\\_dct\[3:0\]\[21:20\]](#). The BaseAddr[17:16] bits are specified by [D18F2x\[5C:40\]\\_dct\[3:0\]\[11:10\]](#).
  - [D18F2x40](#) = 0000\_0001h.
  - [D18F2x44](#) = 0000\_0401h.
  - [D18F2x48](#) = 0000\_0801h.
  - [D18F2x4C](#) = 0000\_0C01h.
- The AddrMask bits to be swapped are the same as the BaseAddr bits defined in the previous step. The AddrMask[29:28] bits are specified by [D18F2x\[6C:60\]\\_dct\[3:0\]\[21:20\]](#). The AddrMask[17:16] bits are specified by [D18F2x\[6C:60\]\\_dct\[3:0\]\[11:10\]](#).
  - [D18F2x60](#) = 0038\_F3E0h.

- D18F2x64 = 0038\_F3E0h.
- 4. If BankSwap is enabled and DCT channel interleaving is enabled on system address bit 8, then the Base and AddrMask bits to be swapped are as follows:
  - D18F2x40 = 0000\_0001h.
  - D18F2x44 = 0000\_0021h.
  - D18F2x48 = 0000\_0041h.
  - D18F2x4C = 0000\_0061h.
  - D18F2x60 = 0038\_FF90h.
  - D18F2x64 = 0038\_FF90h.
- 5. If BankSwap is enabled and DCT channel interleaving is enabled on system address bit 9, then the Base and AddrMask bits to be swapped are as follows:
  - D18F2x40 = 0000\_0001h.
  - D18F2x44 = 0000\_0041h.
  - D18F2x48 = 0000\_0081h.
  - D18F2x4C = 0000\_00C1h.
  - D18F2x60 = 0038\_FF20h.
  - D18F2x64 = 0038\_FF20h.

### 2.9.11.2 Channel Interleaving

The channel memory interleaving mode requires that DIMMs are present on both channels. Channel interleaving is enabled by programming [D18F1x2\[1,0\]\[C,4\]\[DctIntLvEn\]](#) and [D18F2x110\[DctSelIntLvAddr\]](#) to specify how interleaving is performed among the DCTs. If the channels do not have the same amount of DRAM, [D18F1x2\[1,0\]\[8,0\]\[DctBaseAddr\]](#) and [D18F1x2\[1,0\]\[C,4\]\[DctLimitAddr\]](#) are used to configure the interleaved region. See also [2.9.12 \[Memory Hoisting\]](#).

#### 2.9.11.2.1 Four Channel Interleaving

Interleaving 4 DCTs requires one [D18F1x2\[1,0\]\[8,0\]\[DctBaseAddr\]](#) and [D18F1x2\[1,0\]\[C,4\]\[DctLimitAddr\]](#) pair to define the interleave region. [D18F1x2\[1,0\]\[C,4\]\[DctIntLvEn\]](#) is programmed to enable 4 DCTs and [D18F2x110\[DctSelIntLvAddr\]](#) determines the interleave addressing. See [2.9](#) for product specific limitations.

### 2.9.12 Memory Hoisting

Memory hoisting reclaims the otherwise inaccessible DRAM that would naturally reside in memory regions used by MMIO. When memory hoisting is configured by BIOS, DRAM physical addresses are repositioned above the 4 GB address level in the address map. In operation, the physical addresses are remapped in hardware to the normalized addresses used by a DCT.

The region of DRAM that is hoisted is defined to be from [D18F1xF0\[DramHoleBase\]](#) to the 4 GB level. Hoisting is enabled by programming [D18F1xF0 \[DRAM Hole Address\]](#) and configuring the DCTs per the equations in this section.

DramHoleSize is defined in order to simplify the following equations in this section and is calculated as follows:

- Define the DRAM hole region as  $\text{DramHoleSize}[31:24] = 100\text{h} - \text{D18F1xF0}[\text{DramHoleBase}[31:24]]$ .

#### 2.9.12.1 DramHoleOffset Programming

[D18F1xF0\[DramHoleOffset\]](#) is programmed to account for the addresses from [D18F1xF0\[DramHoleBase\]](#) to 4 GB when it falls inside of a [D18F1x2\[1,0\]\[8,0\]\[DctBaseAddr\]](#) and [D18F1x2\[1,0\]\[C,4\]\[DctLimitAddr\]](#) region. See [Figure 3](#) as an example memory population.

- Program `D18F1xF0[DramHoleOffset[31:23]] = {DramHoleSize[31:24], 0b} + {DctBaseAddr[31:27], 0000b};`

**Figure 3: Memory Configuration with Memory Hole inside of Region**

`D18F1xF0[DramHoleOffset]` is unused when the memory hole falls outside of a region. Figure 4 shows an example memory population which uses two memory regions. Region 1 is configured to begin above the memory hole.

**Figure 4: Memory Configuration with Memory Hole outside of Region**

### 2.9.12.2 DctSelBaseOffset Programming

When a DCT is mapped by more than one `D18F1x2[1C:00]` region, `D18F1x2[1,0][8,0][DctOffsetEn]` `D18F1x2[4C:40][DctHighAddrOffset]` are programmed for the second region. In this case, an offset must be applied when forming the normalized address accounting for the DCT addresses mapped by the first region.

Program `D18F1x2[4C:40][DctHighAddrOffset[38:27]] = ((DctLimitAddr + 1) - DctBaseAddr - SizeOf(Memory Holes)) / ((D18F1x2[1,0][C,4][DctIntLvEn] > 0 ? POPCNT(D18F1x2[1,0][C,4][DctIntLvEn]) : 1).`

Examples:

- **Figure 5:** Region 0 maps addresses 0x0 thru 0x7FFF\_FFFF, offset Region 1 which is 2x channel interleaved.
  - `D18F1x208[DctOffsetEn] = 1.`
  - `D18F1x240[DctHighAddrOffset] = ((0x7FFF_FFFF + 1) - 0 - 0) / (1) = 2GB. //DCT 0 offset from Region 0.`
  - `D18F1x244[DctHighAddrOffset] = 0. //DCT 1 is not mapped by Region 0.`

**Figure 5: 2 DCT Channel Interleaved**

- **Figure 6:** Region 0 maps addresses 0x0 thru 0x1\_3FFF\_FFFF which is channel interleaved and contains a 1GB memory hole; offset Region 1 to map the remaining memory.
  - $D18F1x208[DctOffsetEn] = 1$ .
  - $D18F1x240[DctHighAddrOffset] = ((0x1\_3FFF\_FFFF + 1) - 0 - 0x4000\_0000)/(2) = 2GB$ . //DCT 0 offset from Region 0.

**Figure 6: 2 DCT Channel Interleaved with Memory Hole**

### 2.9.13 DRAM CC6/PC6 Storage

DRAM is used to hold the state information of cores entering the CC6 power management state. As part of the system setup if CC6 or PC6 is enabled, BIOS configures a special region of DRAM to hold the state information. In operation, hardware protects this region from general system accesses while allowing the cores access during C-state transitions.

#### 2.9.13.1 Fixed Storage

The size of each special DRAM storage region is defined to be a fixed 16MB. BIOS configures the storage region at the top of the DRAM range, adjusts [D18F1x\[7:4\]\[C,4\]\[DramLimit\]](#) and the processor top of DRAM specified by [MSRC001\\_001A\[TOM\]](#) or [MSRC001\\_001D\[TOM2\]](#) downward accordingly. See [Table 40](#).

After finalizing the system DRAM configuration, BIOS must set [D18F2x118\[LockDramCfg\]](#) = 1 to enable the hardware protection.

**Table 40. Example storage region configuration**

| Node | DRAM Populated | D18F1x[17C:140,7C:40]<br>[DramBase, DramLimit] | CC6<br>DRAM<br>Range  | D18F4x128<br>[CoreStateSa<br>veDestNode] | D18F1x120[DramBaseAddr],<br>D18F1x124[DramLimitAddr] |
|------|----------------|------------------------------------------------|-----------------------|------------------------------------------|------------------------------------------------------|
| 0    | 256 MB         | 0 MB,<br>240 MB - 1                            | 240 MB,<br>256 MB - 1 | 0                                        | 0 MB,<br>256 MB - 1                                  |

### 2.9.14 DRAM On DIMM Thermal Management and Power Capping

Each DCT can throttle commands based on the state of the channel EVENT\_L pin or when D18F2xA4[BwCapEn]=1. The EVENT\_L pin is used for thermal management while D18F2xA4[BwCapEn] limits memory power independent of the thermal management solution.

The EVENT\_L pin for each channel must be wire OR'ed. If all DCTs enabled throttle commands in lockstep using the amount specified in D18F2xA4[CmdThrottleMode] and D18F2xA4[BwCapCmdThrottleMode].

The recommended BIOS configuration for the EVENT\_L pin is as follows:

- BIOS may enable command throttling on a DRAM controller if the platform supports the EVENT\_L pin by programming D18F2xA4[ODTSEn] = 1.
  - The recommended usage is for this pin to be connected to one or more JEDEC defined on DIMM temperature sensors. The DIMM SPD ROM indicates on DIMM temperature sensor support.
  - BIOS configures the temperature sensor(s) to assert EVENT\_L pin active low when the trip point is exceeded and deassert EVENT\_L when the temperature drops below the trip point minus the sensor defined hysteresis.
  - BIOS programs D18F2xA4[CmdThrottleMode] with the throttling mode to employ when the trip point has been exceeded.
  - The hardware enforces a refresh rate of 3.9 us while EVENT\_L is asserted.
- BIOS configures D18F2x8C\_dct[3:0][Tref] based on JEDEC defined temperature range options, as indicated by the DIMM SPD ROM. The two defined temperature ranges are normal (with a case temperature of 85 °C) and extended (with a case temperature of 95 °C).
  - If all DIMMs support the normal temperature range, or if normal and extended temperature range DIMMs are mixed, BIOS programs D18F2x8C\_dct[3:0][Tref] to 7.8 us and D18F2xA4[ODTSEn] = 1. BIOS configures the temperature sensor trip point for all DIMMs according to the 85 °C case temperature specification.
  - If all DIMMs support the extended temperature range, BIOS has two options:
    - a. Follow the recommendation for normal temperature range DIMMs.
    - b. Program D18F2x8C\_dct[3:0][Tref] = 3.9 us and configure the temperature sensor trip point for all DIMMs according to the 95 °C case temperature specification.
- At startup, the BIOS determines if the DRAMs are hot before enabling a DCT and delays for an amount of time to allow the devices to cool under the influence of the thermal solution. This is accomplished by checking the temperature status in the temperature sensor of each DIMM.
- The DCT latched status of the EVENT\_L pin for can be read by system software in D18F2xAC [DRAM Controller Temperature Status].

The relationship between the DRAM case temperature, trip point, and EVENT\_L pin sampling interval is outlined as follows:

- The trip point for each DIMM is ordinarily configured to the case temperature specification minus a guard-band temperature for the DIMM.

- The temperature guardband is vendor defined and is used to account for sensor inaccuracy, EVENT\_L pin sample interval, and platform thermal design.
- The sampling interval is vendor defined. It is expected to be approximately 1 second.

BIOS may enable bandwidth capping on a DRAM controller by setting [D18F2xA4\[BwCapEn\]](#) = 1 and programming [D18F2xA4\[BwCapCmdThrottleMode\]](#) with the throttling mode to employ. The DCT will employ the larger of the two throttling percentages as specified by [D18F2xA4\[BwCapCmdThrottleMode\]](#) and [D18F2xA4\[CmdThrottleMode\]](#) if the EVENT\_L pin is asserted when both [D18F2xA4\[BwCapEn\]](#) = 1 and [D18F2xA4\[ODTSEn\]](#) = 1.

## 2.10 Thermal Functions

Thermal functions HTC, PROCHOT\_L and THERMTRIP are intended to maintain processor temperature in a valid range by:

- Providing a signal to external circuitry for system thermal management like fan control.
- Lowering power consumption by switching to lower-performance P-state.
- Sending processor to the THERMTRIP state to prevent it from damage.

The processor thermal-related circuitry includes (1) the temperature calculation circuit (TCC) for determining the temperature of the processor and (2) logic that uses the temperature from the TCC.

### 2.10.1 The Tctl Temperature Scale

Tctl is a processor temperature control value used for processor thermal management. Tctl is accessible through [D18F3xA4\[CurTmp\]](#). Tctl is a temperature on its own scale aligned to the processors cooling requirements. Therefore Tctl does not represent a temperature which could be measured on the die or the case of the processor. Instead, it specifies the processor temperature relative to the maximum operating temperature, Tctl,max. Tctl,max is specified in the power and thermal data sheet. Tctl is defined as follows for all parts:

A: For  $Tctl = Tctl\_max$  to 255.875: the temperature of the part is  $[Tctl - Tctl\_max]$  over the maximum operating temperature. The processor may take corrective actions that affect performance, such as HTC, to support the return to Tctl range B.

B: For  $Tctl = 0$  to  $Tctl\_max - 0.125$ : the temperature of the part is  $[Tctl\_max - Tctl]$  under the maximum operating temperature.

**Figure 7: Tctl scale**

## 2.10.2 Temperature Slew Rate Control

The temperature slew rate controls in [D18F3xA4](#) are used to filter the processor temperature provided in [D18F3xA4\[CurTmp\]](#). Separate controls are provided for increasing and decreasing temperatures. The latest measured temperature is referred to as Tctlm below.

If downward slew control is enabled ([D18F3xA4\[TmpSlewDnEn\]](#)), Tctl is not updated down unless Tctlm remains below Tctl for a time specified by [D18F3xA4\[PerStepTimeDn\]](#). If at any point before the timer expires Tctlm equals or exceeds Tctl, then the timer resets and Tctl is not updated. If the timer expires, then Tctl is reduced by 0.125. If downward slew control is disabled, then if Tctlm is less than Tctl, Tctl is immediately updated to Tctlm.

The upward slew control works similar to downward slew control except that if Tctlm exceeds Tctl by a value defined by [D18F3xA4\[TmpMaxDiffUp\]](#) then Tctl is immediately updated to Tctlm. Otherwise, Tctlm must remain above Tctl for time specified by [D18F3xA4\[PerStepTimeUp\]](#) before Tctl is incremented by 0.125.

## 2.10.3 Temperature-Driven Logic

The temperature calculated by the TCC is used by HTC, THERMTRIP, and PROCHOT\_L.

### 2.10.3.1 PROCHOT\_L and Hardware Thermal Control (HTC)

The processor *HTC-active state* is characterized by (1) the assertion of PROCHOT\_L, (2) reduced power consumption, and (3) reduced performance. While in the HTC-active state, software should not change the following: All [D18F3x64](#) fields (except for HtcActSts and HtcEn), [MSRC001\\_001F\[DisProcHotPin\]](#). Any change to the previous list of fields when in the HTC-active state can result in undefined behavior. HTC status and control is provided through [D18F3x64](#).

The PROCHOT\_L pin acts as both an input and as an open-drain output. As an output, PROCHOT\_L is driven low to indicate that the HTC-active state has been entered due to an internal condition, as described by the following text. The minimum assertion and deassertion time for PROCHOT\_L is 200 us with a minimum period of 2 ms.

While in the HTC-active state, the following power reduction actions are taken:

- CPU cores are limited to a P-state (specified by [D18F3x64\[HtcPstateLimit\]](#)); see [2.5.3 \[CPU Power Management\]](#)
- The GPU may be placed in a low power state based on the state of [D18F5x178\[ProcHotToGnbEn\]](#)

The processor enters the HTC-active state if all of the following conditions are true:

- [D18F3xE8\[HtcCapable\]](#)=1
- [D18F3x64\[HtcEn\]](#)=1
- PWROK=1
- THERMTRIP\_L=1

and any of the following conditions are true:

- Tctl is greater than or equal to the HTC temperature limit ([D18F3x64\[HtcTmpLmt\]](#)).
- PROCHOT\_L=0

The processor exits the HTC-active state when all of the following are true:

- Tctl is less than the HTC temperature limit ([D18F3x64\[HtcTmpLmt\]](#)).
- Tctl has become less than the HTC temperature limit ([D18F3x64\[HtcTmpLmt\]](#)) minus the HTC hysteresis limit ([D18F3x64\[HtcHystLmt\]](#)) since being greater than or equal to the HTC temperature limit

- (D18F3x64[HtcTmpLmt]).
- PROCHOT\_L=1.

The default value of the HTC temperature threshold (Tctl\_max) is specified in the Power and Thermal Data-sheet.

### 2.10.3.2 Software P-state Limit Control

D18F3x68 [Software P-state Limit] provides a software mechanism to limit the P-state MSRC001\_0061[CurP-stateLimit]. See 2.5.3 [CPU Power Management].

### 2.10.3.3 THERMTRIP

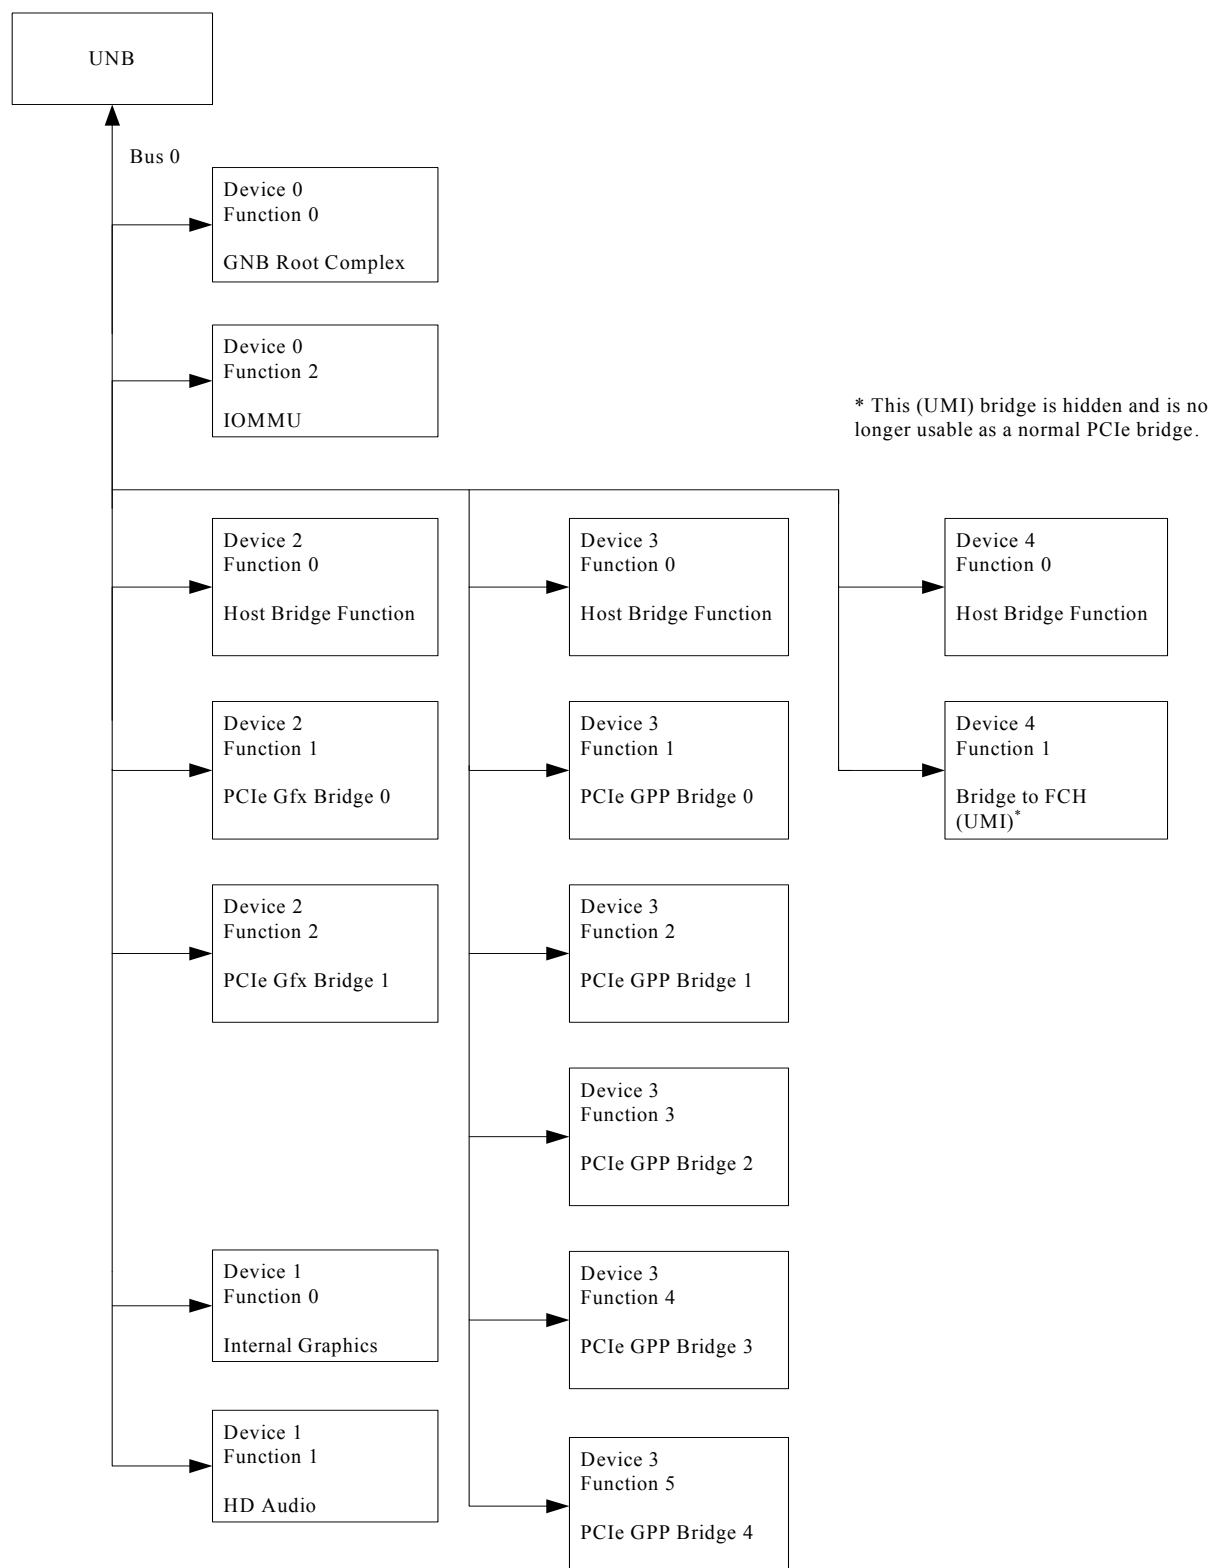

If the processor supports the THERMTRIP state (as specified by D18F3xE4[ThermtEn] or CPUID Fn8000\_0007\_EDX[TTP], which are the same) and the temperature approaches the point at which the processor may be damaged, the processor enters the THERMTRIP state. The THERMTRIP function is enabled after cold reset (after PWROK asserts and RESET\_L deasserts). It remains enabled in all other processor states, except during warm reset (while RESET\_L is asserted). The THERMTRIP state is characterized as follows:

- The THERMTRIP\_L signal is asserted.
- Nearly all clocks are gated off to reduce dynamic power.
- A low-value VID is generated.
- The system is placed into the S5 ACPI state (power off).

A cold reset is required to exit the THERMTRIP state.

## 2.11 Root Complex

### 2.11.1 Overview

**Figure 8: Root complex topology**

## 2.11.2 Interrupt Routing

The GNB includes a fully programmable IOAPIC. The IOAPIC registers are accessed through the [D0F0xF8](#) index and [D0F0xFC](#) data pair registers using two back-to-back config cycles. PCI defined INTx interrupts for each bridge are routed to IOAPIC pins via the bridge interrupt routing registers located at [D0F0xFC\\_x1\[B:0\]](#).

### 2.11.2.1 IOAPIC Configuration

The IOAPIC configuration is performed by the following sequence:

1. Set the base address for the memory mapped registers by programming [D0F0xFC\\_x01](#)[IoapicAddr] and [D0F0xFC\\_x02](#)[IoapicAddrUpper].
2. Enable IOAPIC by programming [D0F0xFC\\_x00](#)[IoapicEnable] = 1.
3. Only if the system is in PIC mode, program [D0F0xFC\\_x00](#)[IoapicSbFeatureEn] = 1. This bit should be programmed to 0 when the system is in APIC mode.

The IOAPIC has a total of 39 interrupt inputs. These inputs are as follows:

- 7 groups of PCIe interrupts each having a 4-bit external interrupt bus (INT A/B/C/D) and a 1-bit bridge interrupt, and
- a 4-bit external interrupt bus from GBIF.

The recommended interrupt routing and swizzling configuration is as shown in [Table 41](#).

**Table 41: Recommended Interrupt Routing and Swizzling Configuration**

| Device  | Register                                   | Setting | Description                                                                        |

### 2.11.3 Links

#### 2.11.3.1 Overview

There are 3 PCIe cores: one 2 x16 core and two 5 x8 cores. There are 8 configurable ports, which can be divided into 2 groups:

- Gfx: Contains 2 x8 ports. Each port can be limited to lower link widths for applications that require fewer lanes. Additionally, the two ports can be combined to create a single x16 link.
- GPP: Contains 1 x4 UMI and 5 General Purpose Ports (GPP).

All PCIe links are capable of supporting Gen1/Gen2 data rates. In addition, the Gfx link is capable of supporting Gen3 data rate.

The FP3 package supports two different voltage levels on the VDDP rail. At the 1.05V nominal setting, the Gfx link can support Gen3 data rate, while at the 0.95V setting, the maximum data rate supported by the Gfx link is Gen2. See 2.9.2 for its effect on DDR3 data rate.

Gfx and GPP ports each have a Type 1 Virtual PCI-to-PCI bridge header in the PCI configuration space mapped to devices according to Figure 8.

Each PCIe and DDI lane is assigned a unique lane ID that software uses to communicate configuration information to the SMU.

#### 2.11.3.2 Link Configurations

Lanes of the Gfx ports can be assigned to IO links or DDI links.  
The following link configurations are supported for the Gfx links:

**Table 42: Supported Gfx Port Configurations**

| Gfx Port Lanes |     |         |       |
|----------------|-----|---------|-------|
| 3:0            | 7:4 | 11:8    | 15:12 |
| x16 Link       |     |         |       |
| x8 Link        |     | x8 Link |       |

**Table 42: Supported Gfx Port Configurations**

| Gfx Port Lanes |         |          |         |
|----------------|---------|----------|---------|
| 3:0            | 7:4     | 11:8     | 15:12   |
| x8 Link        |         | x4 Link  | DDI     |
| x8 Link        |         | DDI      | x4 Link |
| x8 Link        |         | DDI      | DDI     |
| x8 Link        |         | Dual-DVI |         |
| unused         | DDI     | x4 Link  | x4 Link |
| x4 Link        | x4 Link | DDI      | DDI     |
| x4 Link        | x4 Link | Dual-DVI |         |
| x4 Link        | DDI     | x4 Link  | DDI     |
| x4 Link        | DDI     | DDI      | x4 Link |
| x4 Link        | DDI     | DDI      | DDI     |
| x4 Link        | DDI     | Dual-DVI |         |
| x4 Link        | DDI     | x8 Link  |         |
| Dual-DVI       |         | x8 Link  |         |
| Dual-DVI       |         | x4 Link  | x4 Link |
| Dual-DVI       |         | DDI      | x4 Link |
| Dual-DVI       |         | x4 Link  | DDI     |
| Dual-DVI       |         | DDI      | DDI     |
| Dual-DVI       |         | Dual-DVI |         |

To achieve the above configurations, program the following registers:

- Program Gfx function in [D0F0xE4\\_x013\[2:0\]\\_0080](#)[StrapBifLinkConfig].
- Program Gfx PIF 0 and Gfx PIF 1 in the following registers [D0F0xE4\\_x0\[210,11\[3:0\]\]\\_0011](#).
- Program Gfx TX Lane Mux in the following registers [D0F0xE4\\_x013\[3:0\]\\_802\[4:1\]](#).
- Program Gfx RX Lane Mux in the following registers [D0F0xE4\\_x013\[3:0\]\\_802\[8:5\]](#).
- Program OwnSlice in the Gfx registers in [D0F0xE4\\_x013\[3:0\]\\_804\[3:0\]](#)[OwnSlice].

The following DP0/DP1 DDI configurations are supported:

**Table 43: Supported DP0/DP1 DDI Link Configurations**

| Lanes[3:0]          | Lanes[7:4] |
|---------------------|------------|
| DDI                 | DDI        |
| DDI (Dual-link DVI) |            |

The following link configurations are supported for the GPP links:

**Table 44: Supported General Purpose (GPP) Link Configurations**

| D0F0xE4    |            | GPP Port Lane |   |         |         |         |   |   |   |
|------------|------------|---------------|---|---------|---------|---------|---|---|---|
| x0130_0080 | x0111_0011 | 0             | 1 | 2       | 3       | 4       | 5 | 6 | 7 |
| 0000_0001h | 0000_0300h | x4 Link       |   |         |         | x4 Link |   |   |   |
| 0000_0002h | 0000_0203h | x2 Link       |   | x2 Link |         | x4 Link |   |   |   |
| 0000_0003h | 0000_0201h | x2 Link       |   | x1 Link | x1 Link | x4 Link |   |   |   |

## 2.11.4 Root Complex Configuration

### 2.11.4.1 LPC MMIO Requirements

To ensure proper operation of LPC generated DMA requests, the UMI must be configured to send processor generated MMIO writes that target the LPC bus to the FCH as non-posted writes. To ensure this requirement the MMIO address space of the LPC bus must not be included in the ranges specified by [D18F1x\[2CC:2A0,1CC:180,BC:80\] \[MMIO Base/Limit\]](#) and non-posted protocol for memory writes must be enabled using the following sequence before LPC DMA transactions are initiated.

1. Configure the FCH to use the non-posted write protocol. See the FCH register specification for configuration details.
2. Locate the PCIe core that has the UMI link (read [D0F0x64\\_x1F](#) to get location of the FCH).
3. Note that this step should only be performed for the PCIe core with the UMI link (found via step 2 above). Program [D0F0xE4\\_x014\[2:0\]\\_0010\[UmNpMemWrite\]](#) = 1.
4. Program [D0F0x98\\_x06\[UmNpMemWrEn\]](#) = 1.

### 2.11.4.2 Configuration for non-FCH Bridges

BIOS should program the following in non-FCH bridges:

1. Program [D0F0xCC\\_x01\\_ib\[21,1D:19,12:11\]\[CrSEnable\]](#) = 1 for [D0F0xC8\[NbDevIndSel\]](#) = 11h-12h, 19h-1Dh.
2. Program [D0F0xCC\\_x01\\_ib\[21,1D:19,12:11\]\[SetPowEn\]](#) = 1 for [D0F0xC8\[NbDevIndSel\]](#) = 11h-12h, 19h-1Dh.

### 2.11.4.3 Link Configuration and Initialization

Link configuration and initialization is performed by the following sequence:

1. [2.11.4.3.1 \[Link Configuration and Core Initialization\]](#)
2. [2.11.4.3.2 \[Link Training\]](#)
3. [2.11.4.5 \[Link Power Management\]](#)
4. Lock link configuration registers.
  - Program [D0F0xE4\\_x014\[2:0\]\\_0010\[HwInitWrLock\]](#) = 1.
  - Program [D0F0x64\\_x00\[HwInitWrLock\]](#) = 1.
5. IF (external FCH connected through UMI using [D0F0xC8\[NbDevIndSel\]](#)) THEN program [D0F0xCC\\_x01\\_ib\[21,1D:19,12:11\]\[CfgDis\]](#) = 1.

### 2.11.4.3.1 Link Configuration and Core Initialization

Link configuration is done on a per link basis. Lane reversal, IO link/DDI link selection, and lane enablement is configured through this sequence.

1. Place software-reset module into blocking mode:
  - A. Program D0F0xE4\_x013[3:0]\_8062[ConfigXferMode]=0.
  - B. Program D0F0xE4\_x013[3:0]\_8062[BlockOnIdle]=0.
2. If the link is an IO link, Program D0F0xE4\_x014[2:0]\_0011[DynClkLatency]=Fh.
3. Program D0F0xE4\_x013[2:0]\_0080 per Table 44.
4. Program D0F0xE4\_x013[3:0]\_802[4:1] per Table 44.
5. Program D0F0xE4\_x0[210,11[3:0]]\_0010[RxDetectTxPwrMode]=1.
6. Program D0F0xE4\_x0[210,11[3:0]]\_0010[Ln2ExitTime]=000b.
7. Program D0F0xE4\_x013[3:0]\_8013[MasterPciePllA, MasterPciePllB, MasterPciePllC, MasterPciePllD] per Table 44.
8. Initiate core reconfiguration sequence:
  - A. Program D0F0xE4\_x013[3:0]\_8062[ReconfigureEn]=1.
  - B. Program D0F0xE4\_x013[3:0]\_8060[Reconfigure]=1.
  - C. Wait for D0F0xE4\_x013[3:0]\_8060[Reconfigure]==0.
  - D. Program D0F0xE4\_x013[3:0]\_8062[ReconfigureEn]=0.
9. Return software-reset module to non-blocking mode:
  - A. Program D0F0xE4\_x013[3:0]\_8062[ConfigXferMode]=1.
10. Program D[4:2]F[5:1]xE4\_xC1[StrapReverseLanes] if necessary.
11. Program D0F0xE4\_x0[210,11[3:0]]\_0011 per Table 44.
12. Program D0F0xE4\_x0[220,123:120]\_F[E][7:0][8,0]6 per Table 91.
13. For each link mapped to DDI:
  - A. Program D0F0xE4\_x0[210,11[3:0]]\_001[8:7,3:2][PllPowerStateInTxs2]=111b.
  - B. Program D0F0xE4\_x0[210,11[3:0]]\_001[8:7,3:2][PllPowerStateInOff]=111b.
  - C. Program D0F0xE4\_x0[210,11[3:0]]\_001[8:7,3:2][PllRampUpTime]=010b.
14. For each nibble that has no PCIe lanes in use:
  - A. Program D0F0xE4\_x0[210,11[3:0]]\_001[8:7,3:2][PllPowerStateInOff]=111b.
  - B. Program D0F0xE4\_x0[210,11[3:0]]\_001[8:7,3:2][PllPowerStateInTxs2]=111b.
  - C. Program D0F0xE4\_x0[210,11[3:0]]\_001[8:7,3:2][TxPowerStateInTxs2]=111b.
  - D. Program D0F0xE4\_x0[210,11[3:0]]\_001[8:7,3:2][RxPowerStateInRxs2]=111b.
15. For each lane that is not in use, program the corresponding D0F0xE4\_x013[3:0]\_8029[LaneEnable]=0.
16. If the link is a DDI link:
  - A. Program D0F0xE4\_x013[3:0]\_804[3:0][OwnSlice] per Table 42.
17. Configure PIF parings and disable ganged mode for UMI:
  - A. Program D0F0xE4\_x0110\_0011=0000\_0300h.
  - B. Program D0F0xE4\_x0120\_6[3:2][8,0]5[GangedModeEn]=0.

### 2.11.4.3.2 Link Training

Link training is performed on a per link basis. BIOS may train the links in parallel.

### 2.11.4.4 Miscellaneous Features

#### 2.11.4.4.1 Lane Reversal

Normally, the lanes of each port are physically numbered from n-1 to 0 where n is the number of lanes assigned to the port. Physical lane numbering can be reversed according to the following methods:

- To reverse the physical lane numbering for a specific port, program D[4:2]F[5:1]xE4\_xC1[StrapReverseLanes]=1.

- To reverse the physical lane numbering for all ports in the GPP or GFX interfaces, program `D0F0xE4_x014[2:0]_00C0[StrapReverseAll]=1`.

Note that logical port numbering is established during link training regardless of the physical lane numbering.

#### 2.11.4.4.2 Link Speed Changes

Link speed changes can only occur on Gen2 and Gen2/Gen3 capable links. To verify that Gen2/Gen3 speeds are supported verify `D[4:2]F[5:1]x64[LinkSpeed]==02h` or `D[4:2]F[5:1]x64[LinkSpeed]==03h`. Note that Gen3 support is only for the graphics link.

##### 2.11.4.4.2.1 Autonomous Link Speed Changes

To enable autonomous speed changes on a per port basis:

1. Program `D[4:2]F[5:1]x88[TargetLinkSpeed]=2h`.
2. Program `D0F0xE4_x013[2:0]_0[C:8]03[StrapBifDeemphasisSel]=1`.
3. Program `D[4:2]F[5:1]xE4_xA4[LcGen2EnStrap]=1`.
4. Program `D[4:2]F[5:1]xE4_xC0[StrapAutoRcSpeedNegotiationDis]=0`.
5. Program `D[4:2]F[5:1]xE4_xA4[LcMultUpstreamAutoSpdChngEn]=1`.
6. Program `D[4:2]F[5:1]xE4_xA2[LcUpconfigureDis]=0`.

To enable autonomous speed changes on a per port basis for Gen3:

1. Program `D[4:2]F[5:1]x88[TargetLinkSpeed]=3h`.
2. Program `D[4:2]F[5:1]xE4_xA4[LcGen3EnStrap]=1`.
3. Program `D[4:2]F[5:1]xE4_xC0[StrapAutoRcSpeedNegotiationDis]=0`.

##### 2.11.4.4.3 Deemphasis

Deemphasis strength can be changed on a per-port basis by programming `D[4:2]F[5:1]xE4_xB5[LcSelectDeemphasis]`.

#### 2.11.4.5 Link Power Management

##### 2.11.4.5.1 Link States

To enable support for L1 program `D[4:2]F[5:1]xE4_xA0[LcL1Inactivity]=6h`.

To enable support for L0s:

- Program `D[4:2]F[5:1]xE4_xA1[LcDontGotoL0sifL1Armed]=1`.
- Program `D[4:2]F[5:1]xE4_xA0[LcL0sInactivity]=9h`.

##### 2.11.4.5.2 Dynamic Link-width Control

Dynamic link-width control is a power saving feature that reconfigures the link to run with fewer lanes. The inactive lanes are turned off to conserve power.

Each link can switch among widths of: x1, x2, x4, x8, and x16, up to the maximum port width.

The link width is controlled by the following mechanism:

- Up/Down Reconfiguration: The link is retrained according to the PCI Express specification.

The core has the capability to turn off the inactive lanes of trained links. To enable this feature program [D\[4:2\]F\[5:1\]xE4\\_xA2\[LcDynLanesPwrState\]=11b](#).

#### 2.11.4.6 Link Test and Debug Features

##### 2.11.4.6.1 Compliance Mode

To enable Gen1 software compliance mode program [D\[4:2\]F\[5:1\]xE4\\_xC0\[StrapForceCompliance\]=1](#) for each port to be placed in compliance mode.

To enable Gen2 software compliance mode:

1. BIOS enables Gen2 capability by programming [D0F0xE4\\_x014\[2:0\]\\_00C1\[StrapGen2Compliance\]=1](#).
2. Program [D\[4:2\]F\[5:1\]xE4\\_xA4\[LcGen2EnStrap\]=1](#).
3. Program [D\[4:2\]F\[5:1\]x88\[TargetLinkSpeed\]=2h](#) for each port to be placed in compliance mode.
4. Program [D\[4:2\]F\[5:1\]x88\[EnterCompliance\]=1](#) for each port to be placed in compliance mode.

To enable Gen3 software compliance mode:

1. BIOS enables Gen3 capability on the Gfx link by programming [D0F0xE4\\_x0140\\_00C1\[StrapGen3Compliance\]=1](#).
2. Program [D\[4:2\]F\[5:1\]xE4\\_xA4\[LcGen3EnStrap\]=1](#).
3. Program [D\[4:2\]F\[5:1\]x88\[TargetLinkSpeed\]=3h](#) for each port to be placed in compliance mode.
4. Program [D\[4:2\]F\[5:1\]x88\[EnterCompliance\]=1](#) for each port to be placed in compliance mode.

#### 2.11.5 FCH Messages

To replace the wires and messages previously used between the processor and the FCH, upstream and downstream messages are defined through a combination of messages and reads or posted writes of special addresses. These message packets look like regular PCIe packets, but are AMD proprietary packets across the UMI link.

#### 2.11.6 BIOS Timer

The root complex implements a 32-bit microsecond timer (see [D0F0xE4\\_x0132\\_80F0](#) and [D0F0xE4\\_x0132\\_80F1](#)) that the BIOS can use to accurately time wait operations between initialization steps.

To ensure that BIOS waits a minimum number of microseconds between steps BIOS should always wait for one microsecond more than the required minimum wait time.

#### 2.11.7 PCIe Client Interface Control

This interface is accessed through the indexed space registers located at [D0F2xF8](#) within the [Device 0 Function 2 \(IOMMU\) Configuration Registers](#).

BIOS should perform the following steps to initialize the interface:

1. Program [D0F0x64\\_x0D\[PciDev0Fn2RegEn\] = 1h](#).
2. Program credits for the BIF client as follows:
  - A. Program [D0F2xFC\\_x32\\_L1i\[3\]\[DmaNpHaltDis\] = 1h](#).
  - B. Program [D0F2xFC\\_x32\\_L1i\[3\]\[DmaBufCredits\] = 20h](#).
  - C. Program [D0F2xFC\\_x32\\_L1i\[3\]\[DmaBufMaxNpCred\] = 20h](#).
3. Program credits for the PGD client as follows:
  - A. Program [D0F2xFC\\_x32\\_L1i\[0\]\[DmaBufCredits\] = 20h](#).

- B. Program D0F2xFC\_x32\_L1i[0][DmaBufMaxNpCred] = 1Fh.
- 4. Program credits for the INTGEN client as follows:
  - A. Program D0F2xFC\_x32\_L1i[4][DmaNpHaltDis] = 1h.
  - B. Program D0F2xFC\_x32\_L1i[4][DmaBufCredits] = 4h.
  - C. Program D0F2xFC\_x32\_L1i[4][DmaBufMaxNpCred] = 4h.
- 5. Program clock gating as follows:
  - A. Program D0F2xFC\_x33\_L1i[4:0][L1DmaClkgateEn] = 1h.
  - B. Program D0F2xFC\_x33\_L1i[4:0][L1CacheClkgateEn] = 1h.
  - C. Program D0F2xFC\_x33\_L1i[4:0][L1CpslvClkgateEn] = 1h.
  - D. Program D0F2xFC\_x33\_L1i[4:0][L1DmaInputClkgateEn] = 1h.
  - E. Program D0F2xFC\_x33\_L1i[4:0][L1PerfClkgateEn] = 1h.
  - F. Program D0F2xFC\_x33\_L1i[4:0][L1MemoryClkgateEn] = 1h.
  - G. Program D0F2xFC\_x33\_L1i[4:0][L1RegClkgateEn] = 1h.
  - H. Program D0F2xFC\_x33\_L1i[4:0][L1HostreqClkgateEn] = 1h.
  - I. Program D0F2xFC\_x33\_L1i[4:0][L1L2ClkgateEn] = 1h.
  - J. Program D0F2xF4\_x33[CKGateL2ARegsDisable] = 0h.
  - K. Program D0F2xF4\_x33[CKGateL2ADynamicDisable] = 0h.
  - L. Program D0F2xF4\_x33[CKGateL2ACacheDisable] = 0h.
  - M. Program D0F2xF4\_x90[CKGateL2BRegsDisable] = 0h.
  - N. Program D0F2xF4\_x90[CKGateL2BDynamicDisable] = 0h.
  - O. Program D0F2xF4\_x90[CKGateL2BMiscDisable] = 0h.
- 6. Program D0F0x64\_x0D[PciDev0Fn2RegEn] = 0h.

## 2.12 IOMMU

The processor includes an IOMMU revision 2. See the *AMD I/O Virtualization Technology (IOMMU) Specification*.

### 2.12.1 IOMMU Configuration Space

The IOMMU configuration space consists of the following four groups:

- PCI Configuration space. See 3.4 [Device 0 Function 2 (IOMMU) Configuration Registers].
- IOMMU Memory Mapped Register space. See 3.16 [IOMMU Memory Mapped Registers].
- IOMMU L1 Indexed space accessed through D0F2xF8 [IOMMU L1 Config Index].
- IOMMU L2 Indexed space accessed through D0F2xF0 [IOMMU L2 Config Index].

### 2.12.2 IOMMU Initialization

BIOS should perform the following steps to initialize the IOMMU:

1. Program D0F0x64\_x0D[PciDev0Fn2RegEn] = 1h.
2. Program D0F2x44 [IOMMU Base Address Low] and D0F2x48 [IOMMU Base Address High] to allocate a 512K region of MMIO space for IOMMU memory mapped registers. This region of MMIO space is reserved for IOMMU and BIOS must not allocate it for use by system software.
3. Program D0F2x50[IommuHtAtsResv] = 0h.
4. Program D0F2x44[IommuEnable]=1.
5. Program D0F2x70[PrefSupW]=0.
6. Program D[4:2]F[5:1]xE4\_xC1[StrapExtendedFmtSupported]=1 and D[4:2]F[5:1]xE4\_xC1[StrapE2EPrefixEn]=1.
7. Program IOMMUx18[Isoc]=1h if processors support isochronous channel.
8. Program the registers with BIOS recommendations in L1 (D0F2xFC) and L2 (D0F2xF4) indexed space. See 2.11.7 [PCIe Client Interface Control].
9. Check if any PCIe devices in the system support the Phantom Function. For each PCIe core that has a connected device advertising support for the Phantom Function, program D0F2xFC\_x07\_L1i[4:0][0]=0 for the L1 corresponding to that PCIe core.
10. If a PCIe port is hot-plug capable, then program D0F2xFC\_x07\_L1i[4:0][0]=0 for the L1 corresponding to the PCIe core.
11. If at least one PCIE to PCI-x bridge exists on a PCIe port or a HotPlug capable PCIe slot is present on a PCIe port then program D0F2xFC\_x0D\_L1i[4:0][VOQPortBits]=111b for the L1 corresponding to the particular PCIE core.
12. Program the location of the SB into D0F2xF4\_x49 [L2\_SB\_LOCATION]. The program value is required to match the value programmed in D0F0x64\_x1F [FCH Location].
13. Program the port location of the SB into D0F2xFC\_x09\_L1i[4:0] [L1\_SB\_LOCATION] for the L1 corresponding to the iFCH or the PCIE core which FCH is located. Leave register at default value for all L1s corresponding to other PCIE cores.

#### 2.12.2.1 IOMMU L1 Initialization

BIOS should perform the following steps to initialize the IOMMU L1:

1. Program D0F2xFC\_x0C\_L1i[4:0][L1VirtOrderQueues]=4h.
2. Program D0F2xFC\_x32\_L1i[4:0][AtsMultipleRespEn]=1h.
3. Program D0F2xFC\_x32\_L1i[4:0][AtsMultipleL1toL2En]=1h.
4. Program D0F2xFC\_x32\_L1i[4:0][TimeoutPulseExtEn]=1h.

5. Program `D0F2xFC_x07_L1i[4:0][AtsPhysPageOverlapDis]=1h`.
6. Program `D0F2xFC_x07_L1i[4:0][AtsSeqNumEn]=1h`.
7. Program `D0F2xFC_x07_L1i[4:0][SpecReqFilterEn]=1h`.
8. Program `D0F2xFC_x07_L1i[4:0][L1NwEn]=1h`.

### 2.12.2.2 IOMMU L2 Initialization

BIOS should perform the following steps to initialize the IOMMU L2:

1. Program `D0F2xF4_x10[DTCInvalidationSel]=2h`.
2. Program `D0F2xF4_x14[ITCInvalidationSel]=2h`.
3. Program `D0F2xF4_x18[PTCAInvalidationSel]=2h`.
4. Program `D0F2xF4_x50[PDCInvalidationSel]=2h`.
5. Program `D0F2xF4_x80[ERRRuleLock0]=1h`.
6. Program `D0F2xF4_x30[ERRRuleLock1]=1h`.
7. Program `D0F2xF4_x34[L2aregHostPgsize]=2h`.
8. Program `D0F2xF4_x34[L2aregGstPgsize]=2h`.
9. Program `D0F2xF4_x94[L2bregHostPgsize]=2h`.
10. Program `D0F2xF4_x94[L2bregGstPgsize]=2h`.
11. Program `D0F2xF4_x4C[GstPartialPtcCntrl]=3h`.
12. If no internal gfx, program `D0F2xF4_x57[L1ImuIntGfxDis]=1h`.
13. If no external gfx, program `D0F2xF4_x57[0]=1h`.
14. Program `D0F2xF4_x47[TwAtomicFilterEn]=1h`.
15. Program `D0F2xF4_x47[TwNwEn]=1h`.
16. Program `D0F2xF4_x56[CPFlushOnWait]=1h`.
17. Program `D0F2xF4_x56[CPFlushOnInv]=0h`.
18. Program `D0F2xF4_x53[L2bUpdateFilterBypass]=0h`.
19. Program `D0F2xF4_x22[L2aUpdateFilterBypass]=0h`.

### 2.12.2.3 IOMMU SMI Filtering

In order to ensure system management interrupts come from valid peripheral sources, the IOMMU supports an SMI filter (`IOMMUx30[SmiFSup]==01b`). SMI interrupts are filtered according to the values programmed in the SMI filter registers. The registers specify what sources are allowed to send SMI interrupts. `IOMMUx30[SmiFRC]` indicates the number of SMI filter registers available.

The BIOS should set up the SMI filter registers and lock them. These setting will take effect when system software enables the IOMMU and enables SMI filtering. BIOS should perform the following steps to set up SMI filtering:

1. Program `D0F2x70[SmifSupW]=1h`.
2. Choose an SMI filter register from the available set described in `IOMMUx30[SmiFRC]`. Select one register for each SMI source.
3. Program selected SMI filter register to the Device ID of the peripheral issuing the SMI interrupts via `IOMMUx[78,70,68,60][SMIDid]`. Program one register for each SMI source.
4. Program selected SMI filter register to be valid via `IOMMUx[78,70,68,60][SMIDV]`. Program one register for each SMI source.
5. Program selected SMI filter register to be locked via `IOMMUx[78,70,68,60][SMIFlock]`. Program one register for each SMI source.

## 2.13 System Management Unit (SMU)

The system management unit (SMU) is a subcomponent of the northbridge that is responsible for a variety of system and power management tasks during boot and runtime. The SMU contains a microcontroller to assist with many of these tasks.

### 2.13.1 Software Interrupts

The microcontroller can be interrupted to cause it to perform several initialization and runtime tasks. BIOS and ACPI methods can interrupt the SMU to request a specific action using the following sequence:

1. If a service request requires an argument, program `D0F0xBC_xC210_003C`[Argument] with the desired argument.
1. Wait for `D0F0xBC_xC210_0004`[IntDone]==1.
2. Program `D0F0xBC_xC210_0000`[ServiceIndex] to the desired service index and toggle. This may be done in a single write.
3. Wait for `D0F0xBC_xC210_0004`[IntAck]==1.

After performing the steps above, software may continue execution before the interrupt has been serviced. However, software should not rely on the results of the interrupt until the service is complete (see `D0F0xBC_xC210_0004`[IntDone]). Interrupting the SMU with a service index that does not exist results in undefined behavior.

**Table 45: SMU Software Interrupts**

| Service Index | Notes                                                                                                                                                                                                                                                                                                                      |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1Eh           | Description: <b>BIOSMC_MSG_LCLK_DPM_ENABLE</b> . Enables LCLK DPM. See 2.5.6.1.3 [LCLK DPM].                                                                                                                                                                                                                               |
|               | Input: <code>D0F0xBC_x3FDC8</code>                                                                                                                                                                                                                                                                                         |
|               | Output: None.                                                                                                                                                                                                                                                                                                              |

|               | Output: None.                                                                                                                                                                                                                                                                                                              |
| 43h           | Description: <b>BIOSMC_MSG_NBDPM_Enable</b> . Enables NB P-state Adjustments. See 2.5.4.1.1 [Northbridge Dynamic Power Management (NB DPM)].                                                                                                                                                                               |
|               | Input: <code>D0F0xBC_x3F9E8</code>                                                                                                                                                                                                                                                                                         |
|               | Output: <code>D0F0xBC_x3F9EC</code>                                                                                                                                                                                                                                                                                        |

## 2.14 Graphics Processor (GPU)

The APU contains an integrated DX11 compliant graphics processor.

### 2.14.1 Graphics Memory Controller (GMC)

The graphics memory controller is responsible for servicing memory requests from the different blocks within

the GPU and forwarding routing them to the appropriate interface. The GMC is also responsible for translating GPU virtual address to GPU physical addresses and for translating GPU physical addresses to system addresses.

### 2.14.2 Frame Buffer (FB)

The frame buffer is defined as the portion of system memory dedicated for GPU use.

**Table 46: Recommended Frame Buffer Configurations**

| System Memory Size                | Frame Buffer Size |
|-----------------------------------|-------------------|
| < 2 GB                            | 256 MB            |
| >= 2 GB & < 4 GB                  | <u>256 MB</u>     |
| <u>&gt;= 4 GB &amp; &lt; 4 GB</u> | 512 MB            |
| >= 6 GB                           | 1 GB              |

## 2.15 RAS Features

### 2.15.1 Machine Check Architecture

The processor contains logic and registers to detect, log, and correct errors in the data or control paths in each core and the Northbridge. The Machine Check Architecture (MCA) defines the facilities by which processor and system hardware errors are logged and reported to system software. This allows system software to perform a strategic role in recovery from and diagnosis of hardware errors.

Refer to the AMD64 Architecture Programmer's Manual for an architectural overview and methods for determining the processor's level of MCA support. See 1.2 [Reference Documents].

The ability of hardware to generate a machine check exception upon an error is indicated by [CPUID Fn0000\\_0001\\_EDX\[MCE\]](#) or [CPUID Fn8000\\_0001\\_EDX\[MCE\]](#).

#### 2.15.1.1 Machine Check Registers

[CPUID Fn0000\\_0001\\_EDX\[MCA\]](#) or [CPUID Fn8000\\_0001\\_EDX\[MCA\]](#) indicates the presence of the following machine check registers:

- [MSR0000\\_0179 \[Global Machine Check Capabilities \(MCG\\_CAP\)\]](#)
  - Reports how many machine check register banks are supported.
- [MSR0000\\_017A \[Global Machine Check Status \(MCG\\_STAT\)\]](#)
  - Provides basic information about processor state after the occurrence of a machine check error.
- [MSR0000\\_017B \[Global Machine Check Exception Reporting Control \(MCG\\_CTL\)\]](#)
  - Used by software to enable or disable the logging and reporting of machine check errors in the error-reporting banks.

The error-reporting machine check register banks supported in this processor are:

- MC0: Load-store unit (LS), including data cache.
- MC1: Instruction fetch unit (IF), including instruction cache.
- MC2: Combined unit (CU), including L2 cache.
- MC3: Reserved.
- MC4: Northbridge (NB), including the IO link. There is only one NB error reporting bank, independent of the number of cores.
- MC5: execution unit (EX), including mapper/scheduler/retire/execute functions and fixed-issue reorder buffer.
- MC6: Floating point unit (FP).
- The register types within each bank are:
  - [MCi\\_CTL](#), Machine Check Control: Enables error reporting via machine check exception. The [MCi\\_CTL](#) register in each bank must be enabled by the corresponding enable bit in [MCG\\_CTL \(MSR0000\\_017B\)](#).
  - [MCi\\_STATUS](#), Machine Check Status: Logs information associated with errors.
  - [MCi\\_ADDR](#), Machine Check Address: Logs address information associated with errors.
  - [MCi\\_MISC](#), Machine Check Miscellaneous: Log miscellaneous information associated with errors, as defined by each error type.
  - [MCi\\_CTL\\_MASK](#), Machine Check Control Mask: Inhibit detection of an error source unless otherwise specified.

The following table identifies the registers associated with each error-reporting machine check register bank:

**Table 47: MCA register cross-reference table**

| Register Bank (MCi) | MCA Register                 |                              |                              |                              |                              |
|---------------------|------------------------------|------------------------------|------------------------------|------------------------------|------------------------------|
|                     | CTL                          | STATUS                       | ADDR                         | MISC                         | CTL_MASK                     |
| MC0                 | <a href="#">MSR0000_0400</a> | <a href="#">MSR0000_0401</a> | <a href="#">MSR0000_0402</a> | <a href="#">MSR0000_0403</a> | <a href="#">MSRC001_0044</a> |
| MC1                 | <a href="#">MSR0000_0404</a> | <a href="#">MSR0000_0405</a> | <a href="#">MSR0000_0406</a> | <a href="#">MSR0000_0407</a> | <a href="#">MSRC001_0045</a> |
| MC2                 | <a href="#">MSR0000_0408</a> | <a href="#">MSR0000_0409</a> | <a href="#">MSR0000_040A</a> | <a href="#">MSR0000_040B</a> | <a href="#">MSRC001_0046</a> |
| MC3                 | <a href="#">MSR0000_040C</a> | <a href="#">MSR0000_040D</a> | <a href="#">MSR0000_040E</a> | <a href="#">MSR0000_040F</a> | <a href="#">MSRC001_0047</a> |
| MC4                 | <a href="#">MSR0000_0410</a> | <a href="#">MSR0000_0411</a> | <a href="#">MSR0000_0412</a> | <a href="#">MSR0000_0413</a> | <a href="#">MSRC001_0048</a> |
| MC5                 | <a href="#">MSR0000_0414</a> | <a href="#">MSR0000_0415</a> | <a href="#">MSR0000_0416</a> | <a href="#">MSR0000_0417</a> | <a href="#">MSRC001_0049</a> |
| MC6                 | <a href="#">MSR0000_0418</a> | <a href="#">MSR0000_0419</a> | <a href="#">MSR0000_041A</a> | <a href="#">MSR0000_041B</a> | <a href="#">MSRC001_004A</a> |

Corrected, deferred, and uncorrected errors are logged in MCi\_STATUS and MCi\_ADDR as they occur. Uncorrected errors that are enabled in MCi\_CTL result in a Machine Check exception.

Each MCi\_CTL register must be enabled by the corresponding enable bit in [MSR0000\\_017B \[Global Machine Check Exception Reporting Control \(MCG\\_CTL\)\]](#).

MCi\_CTL\_MASK allow BIOS to mask the presence of any error source from software for test and debug. When error sources are masked, it is as if the error was not detected. Such masking consequently prevents error responses and actions.

Each MCA bank implements a number of machine check miscellaneous registers, denoted as MCi\_MISCj, where j goes from 0 to a maximum of 8. If there is more than one MCi\_MISC register in a given bank, a non-zero value in MCi\_MISC0[BlkPtr] points to the contiguous block of additional registers.

The presence of valid information in the first MISC register in the bank (MCi\_MISC0) is indicated by MCi\_STATUS[MiscV]. The presence of valid information in additional implemented MISC registers is indicated by MCi\_MISCj[Val] in the target register.

### 2.15.1.2 Machine Check Errors

The classes of machine check errors are, in priority order from highest to lowest:

- Uncorrected
- Deferred
- Corrected

Uncorrected errors cannot be corrected by hardware and may cause loss of data, corruption of processor state, or both. Uncorrected errors update the status and address registers if not masked from logging in MCi\_CTL\_MASK. Information in the status and address registers from a previously logged lower priority error is overwritten. Previously logged errors of the same priority are not overwritten. Uncorrected errors that are enabled in MCi\_CTL result in reporting to software via machine check exceptions. If an uncorrected error is masked from logging, the error is ignored by hardware (exceptions are noted in the register definitions). If an uncorrected error is disabled from reporting, containment of the error and logging/reporting of subsequent errors may be affected. Therefore, enable reporting of unmasked uncorrected errors for normal operation. Disable reporting of uncorrected errors only for debug purposes.

Deferred errors are errors that cannot be corrected by hardware, but do not cause an immediate interruption in program flow, loss of data integrity, or corruption of processor state. These errors indicate that data has been corrupted but not consumed; no exception is generated because the data has not been referenced by a core or an IO link. Hardware writes information to the status and address registers in the corresponding bank that identifies the source of the error if deferred errors are enabled for logging. If there is information in the status and address registers from a previously logged lower priority error, it is overwritten. Previously logged errors of the same or higher priority are not overwritten. Deferred errors are not reported via machine check exceptions; they can be seen by polling the MCI\_STATUS registers.

Corrected errors are those which have been corrected by hardware and cause no loss of data or corruption of processor state. Hardware writes the status and address registers in the corresponding register bank with information that identifies the source of the error if they are enabled for logging. Corrected errors are not reported via machine check exceptions. Some corrected errors may be reported to software via error thresholding (see [2.15.1.7 \[Error Thresholding\]](#)).

The implications of these categories of errors are:

1. Uncorrected error; hardware did not deal with the problem.
  - Operationally (error handling), action required, because program flow is affected.
  - Diagnostically (fault management), software may collect information to determine if any components should be de-configured or serviced.
2. Deferred error; hardware partially dealt with the problem via containment.
  - Operationally, action optional, because program flow has not been affected. However, steps may be taken by software to prevent access to the data in error.
  - Diagnostically, software may collect information to determine if any components should be de-configured or serviced.
3. Corrected error; hardware dealt with the problem.
  - Operationally, no action required, because program flow is unaffected.
  - Diagnostically, software may collect information to determine if any components should be de-configured or serviced.

Machine check conditions can be simulated to aid in debugging machine check handlers. See [2.15.3 \[Error Injection and Simulation\]](#) for more detail.

### 2.15.1.3 Error Detection, Action, Logging, and Reporting

Error detection is controlled by the MASK registers:

- Error detection for MCA controlled errors is enabled if not masked by MCI\_CTL\_MASK (see [Table 47 \[MCA register cross-reference table\]](#)).
- Error masking is performed regardless of MCA bank enablement in MCG\_CTL ([MSR0000\\_017B](#)).

Error action refers to the hardware response to an error, aside from logging and reporting. Enablement of error action for each error is enumerated in the EAC (Error Action Condition) column of the error descriptions tables as follows:

- D: Detected. The error action is taken if the error is detected (i.e., not masked). These actions occur regardless of whether the MCA bank is enabled in MCG\_CTL.
- E: Enabled. The error action is taken if the error is detected and the bank is enabled in MCG\_CTL.

Error logging refers to the storing of information in the status registers, and is enabled if all of the following are true:

- Error detection is enabled.

- The MCA bank is enabled in MCG\_CTL.

Error reporting refers to active notification of errors to software via machine check exceptions, and is enabled if all of the following are true:

- Error logging is enabled.
- The corresponding enable bit for the error in MCi\_CTL is set to 1.

A machine check exception will be generated if all the following are true:

- The error is uncorrected.
- The error is enabled for reporting.
- CR4.MCE is enabled.

Notes:

1. If CR4.MCE is clear, an error configured to cause a machine check exception will cause a shutdown.
2. If error reporting is disabled, the setting of CR4.MCE has no effect.
3. If an uncorrected error is disabled from reporting, containment of the error and logging/reporting of subsequent errors may be affected. Therefore, unmasked uncorrected errors should be enabled for reporting for normal operation. Uncorrected errors should only be disabled from reporting for debug purposes.
4. Errors not associated with a specific core are reflected to core 0 of the compute unit. The error description tables identify which errors are associated or not associated with a specific core of the compute unit.

Throughout the MCA register descriptions, the terms “enabled” and “disabled” generally refer to reporting, and the terms “masked” and “unmasked” generally refer to logging, unless otherwise noted.

Some logged errors increment a counter in MCi\_MISC, which may trigger an interrupt (see [2.15.1.7 \[Error Thresholding\]](#)). Although no machine check exception will be generated, these notifications can be viewed as “correctable machine check interrupts”.

For debug observability only, [D18F3x180\[ConvertUnCorToCorErrEn\]](#) can be used to log NB uncorrected errors as corrected errors.

### 2.15.1.3.1 MCA conditions that cause Shutdown

The following architectural conditions cause the processor to enter the Shutdown state; see section “Machine-Check Errors” in APM volume 2 for more detail; see [1.2 \[Reference Documents\]](#):

- Attempting to generate an MCE when machine check reporting is disabled at the system level (CR4.MCE=0).
- Attempting to generate an MCE when a machine check is in progress on the same core ([MSR0000\\_017A\[MCIP\]=1](#)).

The following non-architectural conditions cause the processor to enter the Shutdown state:

- EX “Retire dispatch queue parity” error. See [Table 239 \[MC5 Error Descriptions\]](#).
- EX “Mapper checkpoint array parity” error if UC=1. See [Table 239 \[MC5 Error Descriptions\]](#).
- EX “Retire status queue parity” error. See [Table 239 \[MC5 Error Descriptions\]](#)

### 2.15.1.3.2 Error Logging During Overflow

An error to be logged when the status register contains valid data can result in an overflow condition. During error overflow conditions, the new error may not be logged or an error which has already been logged in the status register may be overwritten. For the rules on error overflow, priority, and overwriting, see [MSR0000\\_0401\[Overflow\]](#).

Overflow alone does not indicate a shutdown condition. Uncorrected errors require software intervention. Therefore, when an uncorrected error cannot be logged, critical error information may have been lost, and MCI\_STATUS[PCC] may be set. If PCC is indicated, software should terminate system processing to prevent data corruption (see 2.15.1.6 [Handling Machine Check Exceptions]). If PCC is not indicated, any MCA data lost due to overflow was informational only and not critical to system hardware operation.

The following table indicates which errors are overwritten in the error status registers.

**Table 48: Overwrite Priorities for All Banks**

|             |             |          | Older Error |           |           |           |           |                  |
|-------------|-------------|----------|-------------|-----------|-----------|-----------|-----------|------------------|
|             |             |          | Uncorrected |           | Deferred  |           | Corrected |                  |
|             |             |          | Enabled     | Disabled  | Enabled   | Disabled  | Enabled   | Disabled         |
| Newer Error | Uncorrected | Enabled  | -           | Overwrite | Overwrite | Overwrite | Overwrite | <u>Overwrite</u> |
|             |             | Disabled | -           | -         | Overwrite | Overwrite | Overwrite | Overwrite        |
|             | Deferred    | Enabled  | -           | -         | -         | Overwrite | Overwrite | <u>Overwrite</u> |
|             |             | Disabled | -           | -         | -         | -         | Overwrite | Overwrite        |
|             | Corrected   | Enabled  | -           | -         | -         | -         | -         | <u>Overwrite</u> |
|             |             | Disabled | -           | -         | -         | -         | -         | -                |

#### 2.15.1.4 MCA Initialization

The following initialization sequence must be followed:

- MCI\_CTL\_MASK registers (see Table 47 [MCA register cross-reference table] for list):
  - BIOS must initialize the mask registers to inhibit error detection prior to the initialization of MCI\_CTL and MSR0000\_017B.
  - BIOS must not clear MASK bits that are reset to 1.
- The MCI\_CTL registers must be initialized by the operating system prior to enabling the error reporting banks in MCG\_CTL.

If initializing after a cold reset (see D18F0x6C[ColdRstDet]), then BIOS must clear the MCI\_STATUS MSRs. If initializing after a warm reset, then BIOS should check for valid MCA errors and if present save the status for later diagnostic use (see 2.15.1.6 [Handling Machine Check Exceptions]).

BIOS may initialize the MCA without setting CR4.MCE; this will result in a system shutdown on any machine check which would have caused a machine check exception (followed by a reboot if configured in the chipset). Alternatively, BIOS that wishes to ensure continued operation in the event that a machine check occurs during boot may write MCG\_CTL with all ones and write zeros into each MCI\_CTL. With these settings, a machine check error will result in MCI\_STATUS being written without generating a machine check exception or a system shutdown. BIOS may then poll MCI\_STATUS during critical sections of boot to ensure system integrity. Before passing control to the operating system, BIOS should restore the values of those registers to what the operating system is expecting. (Note that using MCI\_CTL to disable error reporting on uncorrected errors may affect error containment; see 2.15.1.3 [Error Detection, Action, Logging, and Reporting].)

Before ECC memory has been initialized with valid ECC check bits, BIOS must ensure that no memory operations are initiated if MCA reporting is enabled. This includes memory operations that may be initiated by hardware prefetching or other speculative execution. It is recommended that, until all of memory has been initialized with valid ECC check bits, the BIOS either does not have any valid MTRRs specifying a DRAM memory type or does not enable DRAM ECC machine check exceptions.

### 2.15.1.5 Error Code

The MCi\_STATUS[ErrorCode] field contains information used to identify the logged error. [Table 49 \[Error Code Types\]](#) identifies how to decode ErrorCode. The MCi\_STATUS[ErrorCodeExt] field contains detailed, model-specific information that is used to further narrow identification for error diagnosis, but not error handling by software; see [2.15.1.6 \[Handling Machine Check Exceptions\]](#).

For a given error-reporting bank, Error Code Type is used in conjunction with the Extended Error Code (MCi\_STATUS[ErrorCodeExt]) to uniquely identify the Error Type; the value of ErrorCodeExt is unique within Error Code Type. Details for each Error Type are described in the tables accompanying the MCi\_STATUS register for each bank.

- MC0 (LS); [Table 221 \[MC0 Error Signatures\]](#).
- MC1 (IF); [Table 224 \[MC1 Error Signatures\]](#).
- MC2 (CU); [Table 228 \[MC2 Error Signatures\]](#).

### 2.15.1.6 Handling Machine Check Exceptions

A machine check handler is invoked to handle an exception for a particular core. Because MCA registers are generally not shared among cores, the handler does not need to coordinate register usage with handler instances

on other cores. Those few MCA registers which are shared are noted in the register description. (See also [2.4.2.1 \[Registers Shared by Cores in a Compute Unit\]](#).)

For access to the NB MCA registers, [D18F3x44\[NbMcaToMstCpuEn\]](#) allows a single core (the NBC) to access the registers through MSR space without contention from other cores. This organization of registers on a per core basis allows independent execution, simplifies exception handling, and reduces the number of conditions which are globally fatal.

At a minimum, the machine check handler must be capable of logging error information for later examination. The handler should log as much information as is needed to diagnose the error.

More thorough exception handler implementations can analyze errors to determine if each error is recoverable by software. If a recoverable error is identified, the exception handler can attempt to correct the error and restart the interrupted program. An error may not be recoverable for the process or virtual machine it directly affects, but may be containable, so that other processes or virtual machines in the system are unaffected and system operation is recovered; see [2.15.1.6.1 \[Differentiation Between System-Fatal and Process-Fatal Errors\]](#).

Machine check exception handlers that attempt to recover must be thorough in their analysis and the corrective actions they take. The following guidelines should be used when writing such a handler:

- Data collection:
  - All status registers in all error reporting banks must be examined to identify the cause of the machine check exception.
    - Read [MSR0000\\_0179\[Count\]](#) to determine the number of status registers visible to the core. The status registers are numbered from 0 to one less than the value found in [MSR0000\\_0179\[Count\]](#). For example, if the Count field indicates five status registers are supported, they are numbered MC0\_STATUS to MC4\_STATUS. These are generically referred to as MCi\_STATUS.
    - Check the valid bit in each status register (MCi\_STATUS[Val]). The remainder of the status register should be examined only when its valid bit is set.
    - When identifying the error condition and determining how to handle the error, portable exception handlers should examine the following MCi\_STATUS fields: ErrorCode, UC, PCC, CECC, UECC, Deferred, Poison. The expected settings of these and other fields in MCi\_STATUS are identified in the error signatures tables which accompany the descriptions of each MCA status register. See [2.15.1.5 \[Error Code\]](#) for a discussion of error codes and pointers to the error signatures tables.
      - MCi\_STATUS[ErrorCodeExt] should generally not be used by portable code to identify the error condition because it is model specific. ErrorCodeExt is useful in determining the error sub-type for root cause analysis.
    - Error handlers should collect all available MCA information (status register, address register, miscellaneous register, etc.), but should only interrogate details to the level which affects their actions. Lower level details may be useful for diagnosis and root cause analysis, but not for error handling.
- Recovery:
  - Check the valid MCi\_STATUS registers to see if error recovery is possible.
    - Error recovery is not possible when the processor context corrupt indicator (MCi\_STATUS[PCC]) is set to 1.
      - The error overflow status indicator (MCi\_STATUS[Overflow]) does not indicate whether error recovery is possible. See [2.15.1.3.2 \[Error Logging During Overflow\]](#).
    - If error recovery is not possible, the handler should log the error information and return to the operating system for system termination.
  - Check MCi\_STATUS[UC] to see if the processor corrected the error. If UC is set, the processor did not correct the error, and the exception handler must correct the error prior to attempting to restart the interrupted program. If the handler cannot correct the error, it should log the error information and return to

the operating system. If the error affects only process data, it may be possible to terminate only the affected process or virtual machine. If the error affects processor state, continued use of that processor should not occur. See individual error descriptions for further guidance.

- If [MSR0000\\_017A](#)[RIPV] is set, the interrupted program can be restarted reliably at the instruction pointer address pushed onto the exception handler stack if any uncorrected error has been corrected by software. If RIPV is clear, the interrupted program cannot be restarted reliably, although it may be possible to restart it for debugging purposes. As long as PCC is clear, it may be possible to terminate only the affected process or virtual machine.
- When logging errors, particularly those that are not recoverable, check [MSR0000\\_017A](#)[EIPV] to see if the instruction pointer address pushed onto the exception handler stack is related to the machine check. If EIPV is clear, the address is not ensured to be related to the error.
- See [2.15.1.6.1 \[Differentiation Between System-Fatal and Process-Fatal Errors\]](#) for more explanation on the relationship between PCC, RIPV, and EIPV.
- Exit:
  - When an exception handler is able to successfully log an error condition, clear the `MCi_STATUS` registers prior to exiting the machine check handler. Software is responsible for clearing at least `MCi_STATUS[Val]`.
  - Prior to exiting the machine check handler, be sure to clear [MSR0000\\_017A](#)[MCIP]. MCIP indicates that a machine check exception is in progress. If this bit is set when another machine check exception occurs in the same core, the processor enters the shutdown state.

Additional machine check handler portability can be added by having the handler use the `CPUID` instruction to identify the processor and its capabilities. Implementation specific software can be added to the machine check exception handler based on the processor information reported by `CPUID`.

In cases where sync flood is the recommended response to a particular error, a machine check exception cannot be used in lieu of the sync flood to stop the propagation of potentially bad data.

#### 2.15.1.6.1 Differentiation Between System-Fatal and Process-Fatal Errors

The bits `MCi_STATUS[PCC]`, [MSR0000\\_017A](#)[RIPV], and [MSR0000\\_017A](#)[EIPV] form a hierarchy, used by software to determine the degree of corruption and recoverability in the system.

[Table 56](#) shows how these bits are interpreted.

**Table 56: Error Scope Hierarchy**

| PCC | UC | RIPV | EIPV | Deferred | Poison | Comments                                                                                                                                                                                                   |
|-----|----|------|------|----------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | 1  | -    | -    | -        | -      | <b>System fatal error.</b> Signaled via machine check exception, action required. Error has corrupted system state (PCC=1). The error is fatal to the system and the system processing must be terminated. |
| 0   | 1  | 1    | 1    | -        | -      |                                                                                                                                                                                                            |

**Table 56: Error Scope Hierarchy**

| PCC | UC | RIPV | EIPV | Deferred | Poison | Comments                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|----|------|------|----------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | 1  | 0    | -    | -        | 0/1    | <b>Hardware uncorrected, software containable error.</b><br>Signaled via machine check exception, action required. The error is confined to the process, however the process cannot be restarted even if the uncorrected error is corrected by software.<br><br>Poison=1; the error is due to consumption of poison data. If the affected process or virtual machine is terminated, the system may continue operation.            |
| 0   | 0  | -    | -    | 1        | 0      | <b>Deferred error.</b> Action optional. A latent error has been discovered, but not yet consumed; a machine check exception will be generated if the affected data is consumed. Error handling software may attempt to correct this data error, or prevent access by processes which map the data, or make the physical resource containing the data inaccessible.<br>Note: May be detected on a demand access or a scrub access. |
| 0   | 0  | -    | -    | 0        | 0      | <b>Corrected error.</b><br>Signaled via error thresholding mechanisms (2.15.1.7 [Error Thresholding]); no action required.                                                                                                                                                                                                                                                                                                        |

### 2.15.1.7 Error Thresholding

For some types of errors, the hardware maintains counts of the number of errors. When the counter reaches a programmable threshold, an event may optionally be triggered to signal software. This is known as error thresholding. The primary purpose of error thresholding is to help software recognize an excessive rate of errors, which may indicate marginal or failing hardware. This information can be used to make decisions about deconfiguring hardware or scheduling service actions. Counts are incremented for corrected, deferred, and uncorrected errors.

The error thresholding hardware counts only the number of errors; it is up to software to track the errors reported over time in order to determine the rate of errors. Thresholding gives error counts on groups of resources. In order to make decisions on individual resources, a finer granularity of error information, such as MCA information for specific errors, must be utilized in order to obtain more accurate counts and to limit the scope of actions to affected hardware.

Thresholding is performed for “Error Threshold Groups” identified in the list below. For all error threshold groups, some number of corrected errors is expected and normal. There are numerous factors influencing error rates, including temperature, voltage, operating speed, and geographic location. In order to accommodate the various factors, including software latency to respond and track the error thresholding, additional guardband above the normal rates is recommended before error rates are considered abnormal for purposes of hardware action.

The {MC0, MC1, MC2, MC5} error thresholding banks maintains counters, but do not provide interrupts when the threshold is reached; these counters must be polled.

Error thresholding groups:

- MC0
  - MC0 errors are counted and polled via [MSR0000\\_0403](#).
  - MC0 errors are listed in [Table 220 \[MC0 Error Descriptions\]](#).
- MC1
  - MC1 errors are counted and polled via [MSR0000\\_0407](#).
  - MC1 errors are listed in [Table 223 \[MC1 Error Descriptions\]](#).
- MC2
  - MC2 errors are counted and polled via [MSR0000\\_040B](#).
  - MC2 errors are listed in [Table 227 \[MC2 Error Descriptions\]](#).
- DRAM (MC4)
  - Memory errors are counted and polled or reported via [MSR0000\\_0413](#).

DRAM errors are the errors listed in [Table 231 \[MC4 Error Signatures, Part 1\]](#) as “D” (DRAM) in the ETG (Error Threshold Group) column.

- Operating systems can avoid or stop using memory pages with excessive errors.
- Links (MC4)
  - Link errors are counted and polled or reported via [MSRC000\\_0408](#).
  - Link errors are the errors listed in [Table 231 \[MC4 Error Signatures, Part 1\]](#) as “L” (Cache) in the ETG (Error Threshold Group) column.
  - For a link exhibiting excessive errors, it may be possible to reduce errors by lowering the link frequency or reducing the link width (if a bad lane can be avoided). See [2.11 \[Root Complex\]](#) for details and restrictions on configuring links.
- MC5
  - MC5 errors are counted and polled via [MSR0000\\_0417](#).
  - MC5 errors are listed in [Table 240 \[MC5 Error Signatures\]](#).

In rare circumstances, such as two simultaneous errors in the same error thresholding group, it is possible for one error not to increment the counter. In these conditions, MCi\_STATUS[Overflow] may indicate that an overflow occurred, but the error counter may only indicate one error.

### 2.15.1.8 Scrub Rate Considerations

This section gives guidelines for the scrub rate settings available in [D18F3x58 \[Scrub Rate Control\]](#). Scrubbers are used to periodically read cacheline sized data locations and associated tags. There are two primary benefits to scrubbing. First, scrubbing corrects any corrected errors which are discovered before they can migrate into uncorrected errors. This is particularly important for soft errors, which are caused by external sources such as radiation and which are temporary conditions which do not indicate malfunctioning hardware. Second, scrubbers help identify marginal or failed hardware by finding and logging repeated errors at the same locations (see also [2.15.1.7 \[Error Thresholding\]](#)).

There are many factors which influence scrub rates. Among these are:

- The size of memory or cache to be scrubbed
- Resistance to upsets
- Geographic location and altitude
- Alpha particle contribution of packaging
- Performance sensitivity
- Risk aversion

The baseline recommendations in [Table 57](#) are intended to provide excellent protection at most geographic locations, while having no measurable effect on performance. Adjustments may be necessary due to special circumstances. Refer to JEDEC standards for guidelines on adjusting for geographic location.

**Table 57: Recommended Scrub Rates per Node**

| Register            | Memory Size per Node (GB) | Register Setting | Scrub Rate |
|---------------------|---------------------------|------------------|------------|
| D18F3x58[DramScrub] | 0 GB == Size              | 00h              | Disabled   |
|                     | 0 GB < Size <= 1 GB       | 12h              | 5.24 ms    |
|                     | 1 GB < Size <= 2 GB       | 11h              | 2.62 ms    |
|                     | 2 GB < Size <= 4 GB       | 10h              | 1.31 ms    |
|                     | 4 GB < Size <= 8 GB       | 0Fh              | 655.4 us   |
|                     | 8 GB < Size <= 16 GB      | 0Eh              | 327.7 us   |
|                     | 16 GB < Size <= 32 GB     | 0Dh              | 163.8 us   |
|                     | 32 GB < Size <= 64 GB     | 0Ch              | 81.9 us    |
|                     | 64 GB < Size <= 128 GB    | 0Bh              | 41.0 us    |
|                     | 128 GB < Size <= 256 GB   | 0Ah              | 20.5 us    |
|                     | 256 GB < Size             | 09h              | 10.2 us    |

For steady state operation, finding a range of useful scrub rates may be performed by selecting a scrub rate which is high enough to give good confidence about protection from accumulating errors and low enough that it has no measurable effect on performance. The above baselines are made to maximize error coverage without affecting performance and not based on specific processor soft error rates.

For low power states in which the processor core is halted, the power management configuration may affect scrubbing; see [2.8.3 \[Memory Scrubbers\]](#).

### 2.15.1.9 Error Diagnosis

This section describes generalized information and algorithms for diagnosing errors. The primary goal of diagnosis is to identify the failing component for repair purposes. The secondary goal is to identify the smallest possible sub-component for deallocation, deconfiguration, or design/manufacturing root cause analysis.

*Indictment* means identifying the part in error. The simplest form of indictment is *self-indictment*, where the bank reporting the error is the faulty unit. The next simplest form of indictment is *eyewitness indictment*, where the faulty unit is not the bank reporting the error, but is identified unambiguously. Both of these forms can be considered direct indictment; the information for indictment is contained in the MCA error information. If an error is not directly indicted, then identifying the faulty unit is more difficult and may not be an explicit part of the error log.

In general, an address logged in the MCA is useful for direct indictment only if the address identifies a physical location in error, such as a cache index. Logical addresses, while identifying the data, do not identify the location of the data.

If possible, physical storage locations in caches should be checked to determine whether the error is a soft error (a temporary upset of the stored value) or a hard fault (malfunctioning hardware). A location which has had a soft error can be corrected by writing a new value to the location; a reread of the location should see the new value. Hard faults cannot be corrected by writing a new value; the hardware persistently returns the previous value. If such checking is not possible, a grossly simplifying assumption can be made that uncorrected errors are hard and corrected errors are soft. Repeated corrected errors from the same location are an indication that the fault is actually hard.

Determining whether corrected errors represent a hard fault or a soft error requires understanding the access

patterns and any attempts to correct the faulty data in place. An attempt to correct the data in place creates two *epochs*, one before the correction event, and one after. If an error is seen at the same location in two different epochs (especially back-to-back epochs), it is more likely that the cause is a hard fault, since the error has persisted or repeated through an in place correction. The more epochs in which a error is seen, the higher the likelihood of it being caused by a hard fault.

As an example, consider a corrected error found during a read from DRAM. If the DRAM redirect scrubber is enabled (**D18F3x5C**[ScrubReDirEn]), the data in error is corrected in place, and this event conceptually creates a new epoch. If the original fault was due to a soft error, a read of the same data in the new epoch should not encounter a data error. If the original fault was due to a hard fault (e.g., a stuck bit), a read of the data in the new epoch will likely result in another corrected or uncorrected error.

There are numerous correction events that can be used to separate time periods into epochs. These include DRAM redirect scrubs, DRAM sequential scrubs, cache scrubs, cache writes, cache flushes, resets, and others.

#### 2.15.1.9.1 Common Diagnosis Information

A common set of diagnosis information is useful for many problems. [Table 58](#) indicates the minimum set of generally useful diagnostic information that should be collected by software, unless the specifics of the problem are known to be narrower, based on the error code or other information.

It is useful to collect configuration information to ensure that the behavior is not caused by misconfiguration.

**Table 58: Registers Commonly Used for Diagnosis**

| MCA Bank | Status                                       | Configuration                                |
|----------|----------------------------------------------|----------------------------------------------|
| MC0      | MSR0000_0401<br>MSR0000_0402<br>MSR0000_0403 | MSR0000_0400<br>MSRC001_1022<br>MSRC001_0044 |
| MC1      | MSR0000_0405<br>MSR0000_0406<br>MSR0000_0407 | MSR0000_0404                                 |
| MC2      | MSR0000_0409<br>MSR0000_040A<br>MSR0000_040B | MSR0000_0408<br>MSRC001_0046<br>MSRC001_1023 |
| MC3      | Reserved                                     | Reserved                                     |

**Table 58: Registers Commonly Used for Diagnosis**

| MCA Bank | Status                                                                               | Configuration                                                                                             |
|----------|--------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| MC4      | MSR0000_0411<br>MSR0000_0412<br>MSR0000_0413<br>MSRC000_0408<br>D18F3x54<br>D18F2xAC | MSR0000_0410<br>MSRC001_0048<br>D18F3x40<br>D18F3x44<br>D18F3xE4<br>D18F3xE8<br>MSRC001_001F<br>D18F3x180 |

| MC6      | MSR0000_0419<br>MSR0000_041A<br>MSR0000_041B                                         | MSR0000_0418<br>MSRC001_004A                                                                              |

If examining MCA registers after startup, determine the cause of the startup:

- INIT; [D18F0x6C\[InitDet\]](#).
- Cold reset; [D18F0x6C\[ColdRstDet\]](#).
- Warm reset; if not INIT or cold reset.

To see if a link failure occurred, examine [D18F0x\[E4,C4,A4,84\]\[LinkFail\]](#). If set, look for additional information:

- Receipt of a sync, such as during a sync flood, saves a status of Sync Error in MC4\_STATUS.
- CRC error saves a status of CRC Error in MC4\_STATUS. See [D18F0x\[E4,C4,A4,84\]\[CrcErr,CrcFloodEn\]](#).
- Link not present does not save status in MC4\_STATUS. See [D18F0x\[E4,C4,A4,84\]\[InitComplete\]](#).

Other registers may be needed depending on the specific error symptoms.

### 2.15.1.10 Deferred Errors and Data Poisoning

Deferred errors indicate error conditions which could not be corrected, but which require no action (i.e., action optional). Data poisoning marks data which has encountered an uncorrectable error, so that it can be tracked until it is consumed or discarded. Together, data poisoning and deferred errors provide an infrastructure for reducing the severity of errors and the number of system outages for some classes of errors.

Processor cores create poison data and deferred errors as identified in the Error Signatures tables. When poison data or data with an uncorrectable ECC error is consumed, a machine check exception for an uncorrected error is signaled (MCi\_STATUS[UC]). If the data is poison, MCi\_STATUS[Poison] is also set. The NB converts any poison data sent from the core to a machine check exception with error type Compute Unit Data Error. To understand the cause of a machine check exception due to Compute Unit Data Error, examine the core MCA status registers for deferred errors.

The deferred error is logged in the MCA registers for diagnostic purposes at the time the error is discovered

and the data is poisoned. This deferred error can help identify the source of the error. The deferred error is logged independently of any associated poison data machine check. For example, it is possible for a cache eviction to result in a deferred error associated with the cache, and a corresponding machine check exception from the NB which receives the data.

## 2.15.2 DRAM ECC Considerations

DRAM is protected by an error correcting code (ECC). The DRAM error correcting code features an ECC word formed by a symbol based code. The x4 code uses thirty-six 4-bit symbols to make a 144-bit ECC word made up of 128 data bits and 16 check bits.

The x4 code is a single symbol correcting (SSC) and a double symbol detecting (DSD) code. This means the x4 code is able to correct 100% of single symbol errors (any bit error combination within one symbol), and detect 100% of double symbol errors (any bit error combination within two symbols).

Systems supporting ECC and non-ECC memory regions should use the non-ECC memory for the Frame Buffer only.

### 2.15.2.1 ECC Syndromes

For memory errors, the sections below describe how to find the DIMM in error. The process varies slightly according to the ECC code in use. To determine which ECC code is being used, see [D18F3x180\[EccSymbolSize\]](#).

For correctable errors, the DIMM in error is uniquely identified by the error address ([MSR0000\\_0412\[ErrAddr\]](#)) and the ECC syndrome ([MSR0000\\_0411\[Syndrome\[15:8\]\]](#) and [MSR0000\\_0411\[Syndrome\[7:0\]\]](#)). The error address maps to the two DIMMs composing the 128-bit line, and the ECC syndrome identifies one DIMM by identifying the symbol within the line.

#### 2.15.2.1.1 x4 ECC

The use of x4 ECC is indicated in [D18F3x180\[EccSymbolSize\]](#).

The syndrome field uniquely identifies the failing bit positions of a correctable ECC error. Only syndromes identified by [Table 59](#) are correctable by the error correcting code.

Symbols 00h-0Fh map to data bits 0-63; symbols 10h-1Fh map to data bits 64-127; symbols 20-21h map to ECC check bits for data bits 0-63; symbols 22-23h map to ECC check bits for data bits 64-127.

To use [Table 59](#), first find the 16-bit syndrome value in the table. This is performed by using low order 4 bits of the syndrome to select the appropriate error bitmask column. The entire four digit syndrome should then be in one of the rows of that column. The Symbol In Error row indicates which symbol, and therefore which DIMM has the error, and the column indicates which bits within the symbol.

For example, if the ECC syndrome is 6913h, then symbol 05h has the error, and bits 0 and 1 within that symbol are corrupted, since the syndrome is in column 3h (0011b). Symbol 05h maps to bits 23-20, so the corrupted bits are 20 and 21.

**Table 59: x4 ECC Correctable Syndromes**

| Symbol<br>In Error | Error Bitmask |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

### 2.15.3 Error Injection and Simulation

*Error injection* allows the introduction of errors into the system for test and debug purposes. See the following sections for error injection details:

- DRAM: See [2.15.3.1 \[DRAM Error Injection\]](#).
- Link:
  - [D18F3x44](#)[GenLinkSel, GenSubLinkSel, GenCrcErrByte1, GenCrcErrByte0].

*Error simulation* involves creating the appearance to software that an error occurred, and can be used to debug machine check interrupt handlers. This is performed by manually setting the MCA registers with desired values, and then driving the software via INT18. See [MSRC001\\_0015](#)[McStatusWrEn] for making MCA registers writable for non-zero values. When McStatusWrEn is set, privileged software can write non-zero values to the specified registers without generating exceptions, and then simulate a machine check using the INT18 instruction (INTn instruction with an operand of 18). Setting a reserved bit in these registers does not generate an exception when this mode is enabled. However, setting a reserved bit may result in undefined behavior.

#### 2.15.3.1 DRAM Error Injection

This section gives details and examples on injecting errors into DRAM using [D18F3xBC\\_x8](#) [DRAM ECC]. The intent of DRAM error injection is to cause a discrepancy between the stored data and the stored ECC value. Therefore, DRAM error injection is only possible on DRAM which supports ECC, and in which [D18F2x90\\_dct\[3:0\]](#)[DimmEccEn] and [D18F3x44](#)[DramEccEn] are set.

The memory subsystem operates on 64-byte cachelines. The following fields are used to set how the cacheline is to be corrupted in DRAM:

- [D18F3xB8](#)[ArrayAddress] selects a cacheline quadrant (16-byte section) of the cacheline. Each cacheline quadrant is protected by an ECC word. Note that there are special requirements for which bits are used to specify the target quadrant.
- [D18F3xBC\\_x8](#)[ErrInjEn] selects a 16-bit word of the cacheline quadrant selected in ArrayAddress. The 16-bit word identified as ECC[15:0] refers to the bits which store the ECC value; the other 16-bit words address the data on which the ECC is calculated. One or more of these 16-bit words can be selected, and the error bitmask indicated in EccVector is applied to each of the selected words.
- [D18F3xBC\\_x8](#)[EccVector] is a bitmask which selects the individual bits to be corrupted in the 16-bit words selected by ErrInjEn. When selecting the bits to be corrupted for correctable or uncorrectable errors, consider the ECC scheme being used, including symbol size; see [2.15.2 \[DRAM ECC Considerations\]](#) for more details. Note that corrupting more than two symbols may exceed the limits of the ECC to detect the errors; for testing purposes it is recommended that no more than two symbols be corrupted in a single cacheline quadrant.

The distinction between [D18F3xBC\\_x8](#)[DramErrEn] and [D18F3xBC\\_x8](#)[EccWrReq] is that DramErrEn is used to continuously inject errors on every write. This bit is set and cleared by software. EccWrReq is used to inject an error on only one write. This bit is set by software and is cleared by hardware after the error is injected.

When performing DRAM error injection on multi-node systems, [D18F3xB8](#) and [D18F3xBC\\_x8](#) of the NB to which the memory is attached must be programmed.

The following can be used to trigger the injection:

- The memory address is not an explicit parameter of the error injection interface. Once the error injection registers [D18F3xB8](#) and [D18F3xBC](#) are set, the next non-cached access of the appropriate type will trigger the mechanism and apply it to the accessed address. The access should be non-cached so that it is ensured to be seen by the memory controller. Possible methods to ensure a non-cached access include using the appropriate MTRR to set the memory type to UC or turning off caches. If it is important to know the address, then system activity must be quiesced so that the access can take place under careful software control. Once the error injection pattern is set in [D18F3xB8](#) and [D18F3xBC\\_x8](#):
  - Set either [D18F3xBC\\_x8\[EccWrReq\]](#) or [D18F3xBC\\_x8\[DramErrEn\]](#) to enable the triggering mechanism.
  - The next non-cached access of the appropriate type will trigger the mechanism and apply it to the accessed address.

After the error is injected, the data must be accessed in order for the error detection to be triggered. The error address logged in [MSR0000\\_0412](#) will correspond to the cacheline quadrant that contains the error.

When using [MSR0000\\_0411](#) to read `MC4_STATUS` after an error injection and subsequent error detection, be aware that the setting of [D18F3x44\[NbMcaToMstCpuEn\]](#) can cause different cores to see different values. Alternatively, `MC4_STATUS` can be read through the PCI-defined configuration space aliases [D18F3x4C](#) and [D18F3x48](#), which do not return different values to different cores, regardless of the setting of [D18F3x44\[NbMcaToMstCpuEn\]](#).

#### Example 1: Injecting a correctable error:

- Program error pattern:
  - [D18F3xB8\[ArraySelect\]](#)=1000b // select DRAM as target
  - [D18F3xB8\[ArrayAddress\]](#)=000000000b // select 16-byte (128-bit) section
  - [D18F3xBC\\_x8\[ErrInjEn\]](#)=000000001b // select 16-bit word in 16-byte section
  - [D18F3xBC\\_x8\[EccRdReq\]](#)=0 // not a read request
  - [D18F3xBC\\_x8\[EccVector\]](#)=0001h // set bitmask to inject error into only one symbol
- Program error trigger:
  - [D18F3xBC\\_x8\[DramErrEn\]](#)=0 // inject only a single error
  - [D18F3xBC\\_x8\[EccWrReq\]](#)=1 // a write request; enable injection on next write
- Clean up // if programmed for continuous errors
  - [D18F3xBC\\_x8\[DramErrEn\]](#)=0 // inject only a single error

### 2.15.4 GIO RAS

The following register should be programmed to enable RAS features in the GIO.

- Program [D0F0x98\\_x07\[SyncFloodOnParityErr\]](#)=1

### 3 Registers

This section provides detailed field definitions for the core register sets in the processor.

#### 3.1 Register Descriptions and Mnemonics

Each register in this document is referenced with a mnemonic. Each mnemonic is a concatenation of the register-space indicator and the offset of the register. Here are the mnemonics for the various register spaces:

- **IOXXX**: x86-defined input and output address space registers; XXX specifies the hexadecimal byte address of the IO instruction. This space includes IO-space configuration access registers [IOCF8 \[IO-Space Configuration Address\]](#) and [IOCFC \[IO-Space Configuration Data Port\]](#).
- **APICXX0**: APIC memory-mapped registers; XX0 is the hexadecimal byte address offset from the base address. See [2.4.9.1.2 \[APIC Register Space\]](#).
- **CPUID FnXXXX\_XXXX\_EiX[\_xYYY]**: processor capabilities information returned by the CPUID instruction. See [3.18 \[CPUID Instruction Registers\]](#). Each core may only access this information for itself.
- **MSRXXXX\_XXXX**: [MSRs](#); XXXX\_XXXX is the hexadecimal MSR number. This space is accessed through x86-defined RDMSR and WRMSR instructions. Unless otherwise specified there is one set of these registers [Per-core](#). See [2.4.1 \[Compute Unit\]](#).
- **DXFYxZZZ**: PCI-defined configuration space; X specifies the hexadecimal device number (this may be 1 or 2 digits), Y specifies the function number, and ZZZ specifies the hexadecimal byte address (this may be 2 or 3 digits); e.g., D18F3x40 specifies the register at device 18h, function 3, and address 40h. See [2.7 \[Configuration Space\]](#), for details about configuration space.
  - Some register in D18F2xXXX have the `_dct[3:0]` mnemonic suffix. See [2.9.3 \[DCT Configuration Registers\]](#).
- **IOMMUxX\_XXXX**: IOMMU memory mapped registers; X\_XXXX specifies the hexadecimal byte address offset (this may be 2 to 5 digits) from the base address register; The base address for this space is specified by [D0F2x44 \[IOMMU Base Address Low\]](#) and [D0F2x48 \[IOMMU Base Address High\]](#). See [3.16 \[IOMMU Memory Mapped Registers\]](#).
- **PMCxXXX**: core performance monitor events; XXX is the hexadecimal event counter number programmed into [MSRC001\\_020\[A,8,6,4,2,0\]\[EventSelect\]](#); See [2.6.1.1 \[Core Performance Monitor Counters\]](#).
  - When PMCxXXX is followed by `[z:y]` then `UnitMask[z:y]` is being specified.
- **NBPMCxXXX**: NB performance monitor events; XXX is the hexadecimal event counter number programmed into [MSRC001\\_024\[6,4,2,0\]\[EventSelect\]](#); See [2.6.1.2 \[NB Performance Monitor Counters\]](#).
  - When NBPMCxXXX is followed by `[z:y]` then `UnitMask[z:y]` is being specified.

Each mnemonic may specify the location of one or more registers that share the same base definition. A mnemonic that specifies more than one register will contain one or more ranges within braces. The ranges are specified as follows:

- Comma separated lists `[A,B]`: Define specific instances of a register, e.g., `D0F3x[1,0]40` defines two registers `D0F3x40` and `D0F3x140`.
- Colon separated ranges `[A:B]`: Defines all registers that contain the range between A and B. Examples:
  - `D0F3x[50:40]` defines five registers `D0F3x40`, `D0F3x44`, `D0F3x48`, `D0F3x4C`, and `D0F3x50`.
  - `D[8:2]F0x40` defines seven registers `D2F0x40`, `D3F0x40`, `D4F0x40`, `D5F0x40`, `D6F0x40`, `D7F0x40`, and `D8F0x40`.
  - `D0F0xE4_x013[2:0]_0000` defines three registers `D0F0xE4_x0130_0000`, `D0F0xE4_x0131_0000`, and `D0F0xE4_x0132_0000`.
- Colon separated ranges with an explicit step `[A:BstepC]`: Defines the registers from A to B, C defines the offset between registers., e.g., `D0F3x[50:40:step8]` defines three registers `D0F3x40`, `D0F3x48`, and `D0F3x50`.

The processor includes a single set of IO-space and configuration-space registers. However, APIC, CPUID, and MSR register spaces are implemented once per processor core. Access to IO-space and configuration space

registers may require software-level techniques to ensure that no more than one core attempts to access a register at a time.

The following is terminology found in the register descriptions.

**Table 60: Terminology in Register Descriptions**

| Term                | Definition                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BIOS                | Software recommendation syntax. See <a href="#">3.1.2 [Software Recommendation (BIOS, SBIOS)]</a> .                                                                                                                                                                                                                                                                                           |
| SBIOS               |                                                                                                                                                                                                                                                                                                                                                                                               |
| See                 | Reference to remote definition.                                                                                                                                                                                                                                                                                                                                                               |
| Alias               | The alias keyword allows the definition of a soft link between two registers. <ul style="list-style-type: none"><li>• X is an alias of Y: X is a soft link to the register Y.</li><li>• X1, X2 are an alias of Y: Both X1 and X2 are soft links to Y.</li></ul>                                                                                                                               |
| IF                  | Allows conditional definition as a function of register fields. The syntax is: <ul style="list-style-type: none"><li>• IF (conditional-expression) THEN definition ENDIF.</li><li>• IF (conditional-expression) THEN definition ELSE definition ENDIF.</li><li>• IF (conditional-expression) THEN definition ELSEIF (conditional-expression) THEN definition ELSE definition ENDIF.</li></ul> |
| THEN                |                                                                                                                                                                                                                                                                                                                                                                                               |
| ELSEIF              |                                                                                                                                                                                                                                                                                                                                                                                               |
| ELSE                |                                                                                                                                                                                                                                                                                                                                                                                               |
| ENDIF               |                                                                                                                                                                                                                                                                                                                                                                                               |
| Access Types        |                                                                                                                                                                                                                                                                                                                                                                                               |
| Read                | Capable of being read by software.                                                                                                                                                                                                                                                                                                                                                            |
| Read-only           | Capable of being read but not written by software.                                                                                                                                                                                                                                                                                                                                            |
| Write               | Capable of being written by software.                                                                                                                                                                                                                                                                                                                                                         |
| Write-only          | Write-only. Capable of being written by software. Reads are undefined.                                                                                                                                                                                                                                                                                                                        |
| Read-write          | Capable of being written by software and read by software.                                                                                                                                                                                                                                                                                                                                    |
| Set-by-hardware     | Register field is set high by hardware, set low by hardware, or updated by hardware.                                                                                                                                                                                                                                                                                                          |
| Cleared-by-hardware |                                                                                                                                                                                                                                                                                                                                                                                               |
| Updated-by-hardware |                                                                                                                                                                                                                                                                                                                                                                                               |
| Updated-by-SMU      |                                                                                                                                                                                                                                                                                                                                                                                               |
| Write-1-to-clear    | Software must write a 1 to the bit in order to clear it. Writing a 0 to these bits has no affect.                                                                                                                                                                                                                                                                                             |
| Write-1-only        | Software can set the bit high by writing a 1 to it. Writes of 0 have no effect.                                                                                                                                                                                                                                                                                                               |
| Reset-applied       | Takes effect on warm reset.                                                                                                                                                                                                                                                                                                                                                                   |
| GP-read             | GP exception occurs on read.                                                                                                                                                                                                                                                                                                                                                                  |
| GP-write            | GP exception occurs on write.                                                                                                                                                                                                                                                                                                                                                                 |
| GP-read-write       | GP exception occurs on a read or a write.                                                                                                                                                                                                                                                                                                                                                     |
| Per-core            | One instance per core. Only valid for MMIO config space. Writes of these bits from one core only affect that core’s register. Reads return the values appropriate to that core.                                                                                                                                                                                                               |
| Per-compute-unit    | One instance per compute unit. Writes of these bits from one core only affect that compute unit’s register. Reads return the values appropriate to that compute unit. See <a href="#">2.4.2.1 [Registers Shared by Cores in a Compute Unit]</a> .                                                                                                                                             |
| SharedNC            | All cores share the one instance per-compute-unit non-coherently; see <a href="#">2.4.2.1 [Reg-isters Shared by Cores in a Compute Unit]</a> . Valid only with per-compute-unit.                                                                                                                                                                                                              |

**Table 60: Terminology in Register Descriptions**

| Term              | Definition                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Per-L2            | One instance per L2 cache. See <a href="#">CUID Fn8000_001D_EAX_x2</a> [NumSharingCache].                                                                                                                                                                                                                                                                                                                |
| Per-node          | One instance per node. See <a href="#">3.1.1 [Northbridge MSRs In Multi-Core Products]</a> .                                                                                                                                                                                                                                                                                                             |
| Not-same-for-all  | Provide indication as to whether all instances of a given register should be the same across all cores/nodes according to the following equation:<br>SameOnAllCheckEnabled = (Writable && (same-for-all   MSR) && ~(not-same-for-all    UpdatedByHw)). UpdatedByHw = (Updated-by-hardware    set-by-hardware    cleared-by-hardware    set-when-done    cleared-when-done).                              |
| Same-for-all      |                                                                                                                                                                                                                                                                                                                                                                                                          |
| Field Definitions |                                                                                                                                                                                                                                                                                                                                                                                                          |
| Reserved          | Field is reserved for future use. Software is required to preserve the state read from these bits when writing to the register. Software may not depend on the state of reserved fields nor on the ability of such fields to return the state previously written.                                                                                                                                        |
| Unused            | Field is reserved for future use. Software is not required to preserve the state read from these bits when writing to the register. Software may not depend on the state of unused fields nor on the ability of such fields to return the state previously written.                                                                                                                                      |
| MBZ               | Must be zero. If software attempts to set an MBZ bit to 1, a general-protection exception (#GP) occurs.                                                                                                                                                                                                                                                                                                  |
| RAZ               | Read as zero. Writes are ignored, unless RAZ is combined with write-only or write-1-only.                                                                                                                                                                                                                                                                                                                |
| Reset Definitions |                                                                                                                                                                                                                                                                                                                                                                                                          |
| Reset             | The reset value of each register is provided below the mnemonic or in the field description. Unless otherwise noted, the register state matches the reset value when RESET_L is asserted (either a cold or a warm reset). Reset values may include: <ul style="list-style-type: none"><li>• X: an X in the reset value indicates that the field resets (warm or cold) to an unspecified state.</li></ul> |
| Cold reset        | The field state is not affected by a warm reset (even if the field is labeled “cold reset: X”); it is placed into the reset state when PWROK is deasserted. See "Reset" above for the definition of characters that may be found in the cold reset value.                                                                                                                                                |
| Value             | The current value of a read-only field or register. A value statement explicitly defines the field or register as read-only and the value returned under all conditions including after reset events. A field labeled “Value:” will not have a separate reset definition.                                                                                                                                |

### 3.1.1 Northbridge MSRs In Multi-Core Products

MSRs that control Northbridge functions are shared between all cores on the node in a multi-core processor (e.g. [MSRC001\\_001F](#)). If control of Northbridge functions is shared between software on all cores, software must ensure that only one core at a time is allowed to access the shared MSR. Some MSR's are conditionally shared; see [D18F3x44](#)[NbMcaToMstCpuEn].

### 3.1.2 Software Recommendation (BIOS, SBIOS)

The following keywords specify the recommended value to be set by software.

- BIOS: AMD BIOS.
- SBIOS: Platform BIOS.

Syntax: BIOS: integer-expression. Any of the supported tags can be substituted for BIOS.

If “BIOS:” occurs in a register field then the recommended value is applied to the field. If “BIOS:” occurs after a register name but outside of a register field table row then the recommended value is applied to the width of the register.

### 3.1.3 See Keyword (See:)

There is a special meaning applied to the use of “See:” that differs from the use of See not followed by a “:”.

- See, not followed by a “:”, simply refers the reader to a document location that contains related information.
- See followed by a “:” is a shorthand notation that indicates that the definition for this register or register field inherits all properties and definitions from the register or register field that follows “See:”. Any definition local to the register or register field supercedes this inheritance.

“See:” can be used in the following ways:

- Full register width. [CPUID Fn0000\\_0001\\_EAX](#) inherits its full register width definition from [D18F3xFC](#).
- Register field. [MSR0000\\_0277\[PA1MemType\]](#) inherits its definition from PA0MemType, however, the local reset of 4h overrides the inherited PA0MemType reset of 6h.
- Valid values definition. [MSR0000\\_020\[E,C,A,8,6,4,2,0\]\[MemType\]](#), for example, inherits the valid values definition from [Table 216 \[Valid Values for Memory Type Definition\]](#).

### 3.1.4 Mapping Tables

The following mapping table types are defined.

#### 3.1.4.1 Register Mapping

The register mapping table specifies the specific function for each register in a range of registers.

[Table 188](#), for example, specifies that the D18F5x160 function is for NB P-state 0.

#### 3.1.4.2 Index Mapping

The index mapping table is similar to the register mapping table, but specifies the register by index instead of by full register mnemonic.

#### 3.1.4.3 Field Mapping

The field mapping table maps the fields of a range of registers. The rows are the registers that are mapped. Each column specifies a field bit range that is mapped by that column for all registers. The cell at the intersection of the register and the field bit range specifies the suffix that is appended to the register field. “Reserved” specifies that the field is reserved for the register of that row.

#### 3.1.4.4 Broadcast Mapping

The broadcast mapping table maps a register address to a range of register addresses that are written as a group when the broadcast register address is written. The register address is formed by the concatenation of the row address with the column address. The cell at the intersection of the row and column address is a range of register addresses that will be written as a group when the row and column address is written.

### 3.1.4.5 Reset Mapping

The reset mapping table specifies the reset, cold reset, or value for each register in a range of registers.

Table 211 [Reset Mapping for CPUID Fn8000\_0000\_E[D,C,B]X], for example, specifies that the CPUID Fn0000\_0000\_EBX register has a value of 6874\_7541h, with a comment of “The ASCII characters “h t u A””.

### 3.1.4.6 Valid Values

The valid values table defines the valid values for one or more register fields. The valid values table is equivalent in function to the Bits/Description tables in register fields (E.g. MSR0000\_0277[PA0MemType]) and is most often used when the table becomes too large and unwieldy to be included into the register field. (E.g. Table 216 [Valid Values for Memory Type Definition])

### 3.1.4.7 BIOS Recommendations

The BIOS recommendations table defines “BIOS:” recommendations that are conditional and complex enough to warrant a table.

Table 180 [BIOS Recommendations for D18F2x1B[4:0]], for example, specifies the BIOS recommendations for D18F2x1B0[DcqBwThrotWm] and D18F2x1B4[DcqBwThrotWm1, DcqBwThrotWm2]. All cells under the “Condition” header for a given row are ANDed to form the condition for the values to the right of the condition. For example, rows 1-3 and column 1 provide the following equivalent BIOS recommendation:

- D18F2x1B0[DcqBwThrotWm]: BIOS: IF (DdrRate==667) THEN 4h ELSEIF (DdrRate==800) THEN 5h ELSEIF (DdrRate==1066) THEN 6h ELSEIF etc.

## 3.2 IO Space Registers

See 3.1 [Register Descriptions and Mnemonics] for a description of the register naming convention.

### IOCF8 IO-Space Configuration Address

Reset: 0. IOCF8 [IO-Space Configuration Address], and IOCFC [IO-Space Configuration Data Port], are used to access system configuration space, as defined by the PCI specification. IOCF8 provides the address register and IOCFC provides the data port. Software sets up the configuration address by writing to IOCF8. Then, when an access is made to IOCFC, the processor generates the corresponding configuration access to the address specified in IOCF8. See 2.7 [Configuration Space].

IOCF8 may only be accessed through aligned, DW IO reads and writes; otherwise, the accesses are passed to the appropriate IO link. Accesses to IOCF8 and IOCFC received from an IO link are treated as all other IO transactions received from an IO link and are forwarded based on the settings in D18F1x[DC:C0] [IO-Space Base/Limit]. IOCF8 and IOCFC in the processor are not accessible from an IO link.

| Bits  | Description                                                                                                                                                                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | <b>ConfigEn: configuration space enable.</b> Read-write. 1=IO read and write accesses to IOCFC are translated into configuration cycles at the configuration address specified by this register. 0=IO read and write accesses are passed to the appropriate IO link and no configuration access is generated. |
| 30:28 | Reserved.                                                                                                                                                                                                                                                                                                     |
| 27:24 | <b>ExtRegNo: extended register number.</b> Read-write. ExtRegNo provides bits[11:8] and RegNo provides bits[7:2] of the byte address of the configuration register. ExtRegNo is reserved unless it is enabled by MSRC001_001F[EnableCf8ExtCfg].                                                               |

|       |                                                                                                |
|-------|------------------------------------------------------------------------------------------------|
| 23:16 | <b>BusNo: bus number.</b> Read-write. Specifies the bus number of the configuration cycle.     |
| 15:11 | <b>Device: bus number.</b> Read-write. Specifies the device number of the configuration cycle. |
| 10:8  | <b>Function.</b> Read-write. Specifies the function number of the configuration cycle.         |
| 7:2   | <b>RegNo: register address.</b> Read-write. See <a href="#">IOCF8</a> [ExtRegNo].              |
| 1:0   | Reserved.                                                                                      |

#### **IOCF8 IO-Space Configuration Data Port**

---

| Bits | Description                                                    |
|------|----------------------------------------------------------------|
| 31:0 | <b>Data.</b> Read-write. Reset: 0. See <a href="#">IOCF8</a> . |

### 3.3 Device 0 Function 0 (Root Complex) Configuration Registers

See 3.1 [Register Descriptions and Mnemonics] for a description of the register naming convention. See 2.7 [Configuration Space] for details about how to access this space.

#### D0F0x00 Device/Vendor ID

| Bits  | Description                                          |
|-------|------------------------------------------------------|
| 31:16 | <b>DeviceID: device ID.</b> Read-only. Value: 1422h. |
| 15:0  | <b>VendorID: vendor ID.</b> Read-only. Value: 1022h. |

#### D0F0x04 Status/Command

Reset: 0000\_0004h.

| Bits  | Description                                                              |
|-------|--------------------------------------------------------------------------|
| 31:21 | Reserved.                                                                |
| 20    | <b>CapList: capability list.</b> Read-only. 1=Capability list supported. |
| 19:3  | Reserved.                                                                |
| 2     | <b>BusMasterEn: bus master enable.</b> Read-only.                        |
| 1     | <b>MemAccessEn: memory access enable.</b> Read-only.                     |
| 0     | <b>IoAccessEn: IO access enable.</b> Read-only.                          |

#### D0F0x08 Class Code/Revision ID

Reset: 0600\_0000h.

| Bits | Description                                                                                                       |
|------|-------------------------------------------------------------------------------------------------------------------|
| 31:8 | <b>ClassCode: class code.</b> Read-only. Provides the host bridge class code as defined in the PCI specification. |
| 7:0  | <b>RevID: revision ID.</b> Read-only.                                                                             |

#### D0F0x0C Header Type

Reset: 0080\_0000h.

| Bits  | Description                                                                        |
|-------|------------------------------------------------------------------------------------|
| 31:24 | Reserved.                                                                          |
| 23    | <b>DeviceType.</b> Read-only. 0b=Single function device. 1b=Multi-function device. |
| 22:16 | <b>HeaderType.</b> Read-only.                                                      |
| 15:8  | <b>LatencyTimer.</b> Read-only.                                                    |
| 7:0   | <b>CacheLineSize.</b> Read-only.                                                   |

**D0F0x2C Subsystem and Subvendor ID**

| Bits  | Description                                         |
|-------|-----------------------------------------------------|
| 31:16 | <b>SubsystemID</b> . Read-only. Value: 1410h.       |
| 15:0  | <b>SubsystemVendorID</b> . Read-only. Value: 1022h. |

**D0F0x34 Capabilities Pointer**

Reset: 0000\_0000h.

| Bits | Description                                                                   |
|------|-------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                     |
| 7:0  | <b>CapPtr: capabilities pointer</b> . Read-only. There is no capability list. |

**D0F0x48 NB Header Write Register**

Reset: 0000\_0080h.

| Bits | Description                                                                                                                                                                                     |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                                       |
| 7    | <b>DeviceType: device type</b> . Read-write. This field sets the value in the corresponding field in <a href="#">D0F0x0C[DeviceType]</a> . 0b=Single function device. 1b=Multi-function device. |
| 6:0  | Reserved.                                                                                                                                                                                       |

**D0F0x4C PCI Control**

Reset: 0000\_0000h.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| D0F0x64_x34 | 0000_001Bh | Program [7:3]DevNum, [2:0]FnNum to map to PortC of PPD. |
| D0F0x64_x35 | 0000_001Ch | Program [7:3]DevNum, [2:0]FnNum to map to PortD of PPD. |
| D0F0x64_x36 | 0000_001Dh | Program [7:3]DevNum, [2:0]FnNum to map to PortE of PPD. |
| D0F0x64_x37 | 0000_0021h | Program [7:3]DevNum, [2:0]FnNum to map to PortA of PSD. |
| D0F0x64_x38 | 0000_0022h | Program [7:3]DevNum, [2:0]FnNum to map to PortB of PSD. |
| D0F0x64_x39 | 0000_0023h | Program [7:3]DevNum, [2:0]FnNum to map to PortC of PSD. |
| D0F0x64_x3A | 0000_0024h | Program [7:3]DevNum, [2:0]FnNum to map to PortD of PSD. |
| D0F0x64_x3B | 0000_0025h | Program [7:3]DevNum, [2:0]FnNum to map to PortE of PSD. |

Software can only utilize device and function number combinations that are used by other (local) PCIe bridges.

This effectively allows swapping of device and function numbers between bridges.

### D0F0xB8 SMU Index Address

The index/data pair registers, [D0F0xB8](#) and [D0F0xBC](#), are used to access the registers at [D0F0xBC\\_x\[FFFFFFFF:00000000\]](#). To access any of these registers, the address is first written into the index register, [D0F0xB8](#), and then the data is read from or written to the data register, [D0F0xBC](#).

**D0F0xC8 DEV Index Address**

The index/data pair registers, [D0F0xC8](#) and [D0F0xCC](#) are used to access the registers at [D0F0xCC\\_x\[FF:00\]](#). To access any of these registers, the address is first written into the index register, [D0F0xC8](#), and then the data is read from or written to the data register, [D0F0xCC](#). Specific IOC bridges (Device/Function) are selected using the [D0F0xC8\[NbDevIndSel\]](#) field and enumerated as *\_ib[21,1D:19,12:11]* in the indexed register's mnemonic.

### D0F0xE0 Link Index Address

Reset: 0130\_8001h.

**D0F0xE0** and **D0F0xE4** are used to access **D0F0xE4\_x**[FFFF\_FFFF:0000\_0000]. To read or write to one of these register, the address is written first into the address register **D0F0xE0** and then the data is read from or written to the data register **D0F0xE4**.

The phy index registers (**D0F0xE4\_x0**[2:1]xxx\_xxxx]) mapping to a specific phy, pin or pin group is shown in a table in the register definition. For example, to perform a read or write operation to configure Gfx phy 0 (P\_GFX\_[T,R]X[P,N][7:0] pin group) compensation, software should program **D0F0xE0**[31:0]=0120\_0000h. Accessing any register number that is not listed in the mapping table may result in undefined behavior.

Some phy registers support broadcast write operations to groups of 4 or 8 lanes. For example, to perform broadcast write operation to configure Gfx Link[3:0] (P\_GFX\_RX[P,N][3:0] lanes) receiver phase loop filter, software should program **D0F0xE0**[31:0]=0120\_5602h.

### 3.3.2 Phy Registers

There are three categories of phy registers: 3.3.2.1 [Global Phy Control Registers], receiver lane control registers and transmitter lane control registers.

#### 3.3.2.1 Global Phy Control Registers

Each global phy control register may have one instance per phy or two instances per phy (one per nibble). When a global register is implemented per phy the mapping to signal pins is shown in Table 67. When a global register is implemented per nibble the mapping to pins is shown in Table 67.

**Table 67: Per phy register addresses to pin mappings**

| D0F0xE0[31:0]  | Pin Names                                                   |
|----------------|-------------------------------------------------------------|
| 0120_[2:0]xxxh | Gfx Links[7:0]: P_GFX_[T,R]X[P,N][7:0]                      |
| 0220_[2:0]xxxh | Gfx Links[15:8]: P_GFX_[T,R]X[P,N][15:8]                    |
| 0121_[2:0]xxxh | GPP Links: P_GPP_[T,R]X[P,N][7:0]                           |
| 0122_[2:0]xxxh | FCH ports: DDI 0: DP0_TX[P,N][3:0] & P_UMI_[T,R]X[P,N][3:0] |

### **D0F0xE4\_x0[220,123:120]\_000[2:1] Phy Impedance Control**

Updates to these registers that result in a change to impedance may not take effect in the phy for up to 2 micro-seconds after the update to this register completes.

**Table 70: Recommended Ron settings**

#### **[D0F0xE4\\_x0\[220,123:120\]\\_000\[C:B\]](#) Phy Serial Bus Packet Control**

This register provides control to enable or disable various fields contained in the phy serial bus primary control

packet, the margining packet and the miscellaneous control packet.

### 3.3.2.2 Phy Receiver Lane Control Registers

Each receiver lane has a group of registers for controlling the operation of the lane. The mapping from address

register to receiver lane is shown in Table 73. Multiple receiver lanes may be written at the sametime using per nibble and per byte broadcast write addresses. The mapping from broadcast address to receiver lanes is shown in Table 74.

#### D0F0xE4\_x0[220,123:120]\_5:4[7:6,3:0][8,0]2 Phy Receiver Phase Loop Filter Control

**Figure 9: Phy recovered clock and sample clock**

When the link is in a mode that relies on dynamic phase alignment (automatic sample-clock correction), then the processor generates a recovered clock for each lane based on transitions in the lane. The ideal recovered clock transitions at exactly the same time as the transitions in the lane. Phase detection logic detects if the recovered clock transitions before or after the lane transition. The digital loop filter (DLF) is logic that adjusts the phase of the recovered clock such that its transitions match the transition time of the lane as much as possible. The DLF counts the number of times the lane transitions before the recovered clock versus after to determine whether the recovered clock phase requires adjustment. The DLF uses an 8-bit counter, called the loop filter counter (LFC) for this purpose. The LFC controls are included in this register. They specify DLF behavior as follows:

- LfcMax is programmed to be greater than LfcMin.

- The LFC is initialized to LfcMin.
- The LFC is updated periodically. The logic keeps a tally of the number of lane transitions occurring before and after the recovered clock transition within each update period.
- To start, if there is a net lane transition occurs after the recovered clock transition within the update period, the LFC is incremented by the net value; on the other hand, if there is a net lane transition occurs before the recovered clock transition, the LFC is decremented. However, if the LFC is ever decremented while it is zero, these rules are reversed (and the LFC is incremented instead). Thus, if there is a phase correction needed, the LFC trends either upward or downward; if it trends downward, it hits zero and then trends upward again.
- If the LFC reaches LfcMax value, then (1) the phase of the recovered clock is adjusted in the appropriate direction, (2) the LFC is set to the LfcMin value.

The LfcMin and LfcMax fields are designed to improve the stability of the recovered clock phase while improving the response time for multiple phase updates in the same direction. For example, if the recovered clock phase needs several adjustments in the same direction, then the LFC increments until it hits LfcMax value and then be set to LfcMin (and trigger a phase adjustment); then it would increment to LfcMax value again to trigger the next phase adjustment. If, however, the next phase adjustment needs to be in the opposite direction, the LFC would decrement to zero, change direction, and then increment up to LfcMax again. In this way, phase adjustments in the same direction occur more quickly than phase adjustments in the opposite direction of the prior phase adjustment.

The nominal sample clock is offset by 90 degrees from the *recovered clock*.

### D0F0xE4\_x0[220,123:120]\_[5:4][7:6,3:0][8,0]5 Phy Receiver Timing Margin Test

The built in jitter injection test mode is useful for checking the clock data recovery tracking bandwidth of the receiver. By forcing the sample clock to move from the lock position by a controlled amount and then observing the time it takes to recover, the tracking rate and bandwidth can be estimated. This register provides the control of the test mode.

The jitter injection test mode works as follows.

- The circuit is clocked by a jitter injection clock derived from dividing the link forwarded clock by 2.5; for example, if the link speed is 5.2GT/s and the link forwarded clock frequency is 2.6GHz, the jitter injection clock frequency becomes 1.04GHz.
- There are 2 phases, the on phase and the off phase. It starts with the on phase once the test mode is enabled.
- During the on phase, at every tick of jitter injection clock, the sample clock is moved away from the nominal lock position by  $1/96 \cdot UI$ .
- The direction of adjustment is specified by JitterInjDir.
- The on phase adjustment continues for a number of times as specified by JitterInjOnCnt.
- Then the adjustment turns off for a duration specified by {JitterInjOffCnt, JitterInjOnCnt} \* jitter injection clock period, this is known as the off phase. During this time, clock data recovery resumes to try to adjust the position of the sample clock back to the center of the data eye.
- The off phase is followed by the on phase again. The process continues to alternate between the on phase and the off phase until the jitter injection test mode is disabled.

In addition, the JitterInjHold bit may be set to inject a hold state at the end of the on phase. This stops clock data recovery from resuming after the on phase, hence holding the sample clock at its last adjusted position until the JitterInjHold bit is cleared. This test mode may be useful for margining the width of the input data eye.

This margining mechanism is not characterized for precision jitter adjustments or measurements.

#### D0F0xE4\_x0[220,123:120]\_[5:4][7:6,3:0][8,0]6 Phy Receiver DFE and DFR Control

The processor supports decision feedback restore (DFR), a function that enables on-chip AC coupling on the receiver path, to improve the receiver's ability to operate over a longer channel. In this mode, the receiver on the processor must be programmed with the expected peak single-ended DC voltage level over the single-ended DC common mode voltage level, as seen by the receiver, when a static 1 or 0 is driven. For example, without deemphasis at nominal supply voltage of 1.2V, the peak single ended voltage is expected to be 300mV ideally above the single ended DC common mode voltage level. The value is dependent on the deemphasis setting of the transmitter on the other end of the channel.

**Table 79: BIOS Recommendations for D0F0xE4\_x0[220,123:120]\_[5:4][7:6,3:0][8,0]6[VdcDac]**

| Far-device deemphasis setting | VdcDac |
|-------------------------------|--------|
| No deemphasis                 | 4Dh    |
| -2dB postcursor               | 3Dh    |
| -3dB postcursor               | 36h    |
| -5dB postcursor               | 2Bh    |
| -6dB postcursor               | 27h    |
| -7dB postcursor               | 22h    |
| -8dB postcursor               | 1Fh    |
| -9dB postcursor               | 1Bh    |
| -11dB postcursor              | 16h    |

Decision feedback equalization (DFE) can be enabled to enhance link operation. Once enabled, the receiver uses the logic level of the previous data bit to adjust the voltage threshold of the sampler in the direction that causes the sampler to switch sooner when the data bit transitions to the opposite logic level for the next bit. The control and DFE voltage level are included in this register.

### 3.3.2.3 Phy Transmitter Lane Control Registers

Each transmitter lane has a group of registers for controlling the operation of the lane. The mapping from address register to transmitter lane is shown in Table 84. Multiple transmitter lanes may be written at the same time using per nibble and per byte broadcast write addresses. The mapping from broadcast address to transmitter lanes is shown in Table 85.

**Table 84: Phy per transmitter lane register addresses**

**D0F0xF8 Northbridge IOAPIC Index**

Reset: 0000\_0000h. The index/data pair registers, [D0F0xF8](#) and [D0F0xFC](#), are used to access the registers at [D0F0xFC\\_x\[FF:00\]](#). To access any of these registers, the address is first written into the index register, [D0F0xF8](#), and then the data is read from or written to the data register, [D0F0xFC](#).

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:27 | <b>IommuMsiNumPpr.</b> Read-only. Reset: 0. This field must indicate which MSI vector is used for the interrupt message generated by the IOMMU for the peripheral page service request log when <a href="#">IOMMUx30</a> [PprSup]=1. This field must be 0 when <a href="#">IOMMUx30</a> [PprSup]=0. For MSI there can be only one IOMMU so this field must be 0. This interrupt is not remapped by the IOMMU. |
| 26:23 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                     |
| 22    | <b>IommuHtAtsResv.</b> IF ( <a href="#">D0F2x44</a> [IommuEnable]) THEN Read-only. ELSE Read-write. ENDIF. Indicates the MSI vector used for interrupt messages generated by the IOMMU.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |      |             |           |           |      |          |           |           |     |           |         |           |         |           |         |           |     |          |         |           |

#### D0F2x54 IOMMU MSI Capability Register

| Bits  | Description                                                                                                      |
|-------|------------------------------------------------------------------------------------------------------------------|
| 31:24 | Reserved.                                                                                                        |
| 23    | <b>Msi64En.</b> Read-only. Reset: 1. 1=64-bit MSI addressing is supported                                        |
| 22:20 | <b>MsiMultMessEn.</b> Read-write. Reset: 0. Specifies the number of MSI messages assigned to this function.      |
| 19:17 | <b>MsiMultMessCap.</b> Read-only. Reset: 0. Specifies the number of MSI messages requested by this function.     |
| 16    | <b>MsiEn.</b> Read-write. Reset: 0. 1=Enables MSI for this function and causes legacy interrupts to be disabled. |
| 15:8  | <b>MsiCapPtr.</b> Read-only. Reset: 64h. Pointer to the next capability register offset.                         |
| 7:0   | <b>MsiCapId.</b> Read-only. Reset: 5h. Indicates that this is the MSI capability.                                |

**D0F2x58 IOMMU MSI Address Low**

| Bits | Description                                                                                                             |
|------|-------------------------------------------------------------------------------------------------------------------------|
| 31:2 | <b>MsiAddr[31:2]</b> . Read-write. Reset: 0. This register specifies the lower address bits used to issue MSI messages. |
| 1:0  | Reserved.                                                                                                               |

**D0F2x5C IOMMU MSI Address High**

| Bits | Description                                                                                                              |
|------|--------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>MsiAddr[63:32]</b> . Read-write. Reset: 0. This register specifies the upper address bits used to issue MSI messages. |

**D0F2x60 IOMMU MSI Data**

| Bits  | Description                                                                                       |
|-------|---------------------------------------------------------------------------------------------------|
| 31:16 | Reserved.                                                                                         |
| 15:0  | <b>MsiData</b> . Read-write. Reset: 0. This register specifies the data issued with MSI messages. |

**D0F2x64 IOMMU MSI Mapping Capability**

| Bits  | Description                                                                                                          |
|-------|----------------------------------------------------------------------------------------------------------------------|
| 31:27 | <b>MsiMapCapType</b> . Read-only. Reset: 15h. Indicates the MSI Mapping Capability.                                  |
| 26:18 | Reserved.                                                                                                            |
| 17    | <b>MsiMapFixd</b> . Read-only. Reset: 1. 1=MSI interrupt mapping range is not programmable.                          |
| 16    | <b>MsiMapEn</b> . Read-only. Reset: 1. Always set to 1 to indicate that the MSI Mapping Capability is always enabled |
| 15:8  | <b>MsiMapCapPtr</b> . Read-only. Reset: 0. Points to the next capability list item                                   |
| 7:0   | <b>MsiMapCapId</b> . Read-only. Reset: 8h. Indicates a link capability list item                                     |

**D0F2x6C IOMMU Control**

| Bits  | Description                                                                                                    |

### D0F2xF0 IOMMU L2 Config Index

The index/data pair registers, [D0F2xF0](#) and [D0F2xF4](#) are used to access the registers at [D0F2xF4\\_x](#)[FF:00].

To access any of these registers, the address is first written into the index register, [D0F2xF0](#), and then the data is read from or written to the data register, [D0F2xF4](#). See [2.12.1 \[IOMMU Configuration Space\]](#).

| Bits | Description                               |

|------|--------------------------------------------------------------------|
| 31:0 | <b>L2STATUS0</b> . Read-only. Reset: 0. Internal IOMMU L2A status. |

**D0F2xF4\_x0C L2\_CONTROL\_0**

| Bits  | Description                                                                                                                                                                                                                                                                            |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>IFifoClientPriority</b> . Read-write. Reset: 0. Each bit of this register controls whether the corresponding L1 client is arbitrated as high priority or not. Not all implementations will use all of the priority bits due to a lower number of clients versus the register width. |
| 23:20 | <b>IFifoBurstLength</b> . Read-write. Reset: 1. Sets the burst length when arbitrating between clients coming into the L2.                                                                                                                                                             |
| 19    | Reserved.                                                                                                                                                                                                                                                                              |
| 18    | <b>FLTCMBPriority</b> . Read-write. Reset: 0. 0=Round-robin arbitration between cache responses and table-walker responses at the fault combiner. . 1=Table-walker responses always win arbitration at the fault combiner.                                                             |
| 17:12 | <b>IFifoCMBCredits</b> . Read-write. Reset: 4h. Controls the initial number of credits for the ififo to fault/CMB interface. Credits are loaded whenever the register value changes. This register may only be programmed when IOMMU is not enabled to preserve correct operation.     |
| 11    | <b>SIDEPTEOnAddrTransExcl</b> . Read-write. Reset: 0. 0=Caches return DTE to L1 on an address translation exclusion range access. 1=Caches return PTE to L1 on an address translation exclusion range access.                                                                          |
| 10    | <b>SIDEPTEOnUntransExcl</b> . Read-write. Reset: 0. 0=Caches return DTE to L1 on an untranslated exclusion range access . 1=Caches return PTE to L1 on an untranslated exclusion range access.                                                                                         |
| 9:4   | <b>IFifoTWCredits</b> . Read-write. Reset: 4h. Controls the initial number of credits for the ififo to TW interface. Credits are loaded whenever the register changes value. This register may only be programmed when IOMMU is not enabled to preserve correct operation.             |

|   |                                                                                                                                                                                                                                                                                                          |
|---|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3 | <b>DTCHitVZeroOrIVZero.</b> Read-write. Reset: 0. 0=A DTE is refetched if a DTE with V=0 for a memory request or IV=1 for an interrupt request is hit in the DTC . 1=A DTE is not refetched if a DTE with V=0 for a memory request or IV=1 for an interrupt request is hit in the DTC. This DTE is used. |
| 2 | <b>AllowL1CacheATSRsp.</b> Read-write. Reset: 0. 0=L2 does not allow L1 to cache responses to ATS address translation requests . 1=L2 allows L1 to cache responses to ATS address translation requests.                                                                                                  |
| 1 | <b>AllowL1CacheVZero.</b> Read-write. Reset: 0. 0=L2 does not allow L1 to cache DTEs where V=0 . 1=L2 allows L1 to cache DTEs where V=1. L1 stores IR and IW as if they are both set to 1.                                                                                                               |
| 0 | <b>PTCAddrTransReqCheck.</b> Read-write. Reset: 0. 0=Address translation requests do not check the PTC . 1=Address translation requests check the PTC.                                                                                                                                                   |

### D0F2xF4\_x0D L2\_CONTROL\_1

| Bits  | Description                                                                                                                                                                                                                                                                                       |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>PerfThreshold.</b> Read-write. Reset: 0. Fifo threshold level used to calculate certain performance counter values.                                                                                                                                                                            |
| 23:17 | Reserved.                                                                                                                                                                                                                                                                                         |
| 16    | <b>SeqInvBurstLimitEn.</b> Read-write. Reset: 1. Enable stalling L2 requests to allow invalidation cycles to make forward progress based upon SeqInvBurstLimitInv and SeqInvBurstLimitL2Req.                                                                                                      |
| 15:8  | <b>SeqInvBurstLimitL2Req.</b> Read-write. Reset: 8h. Sets the number of consecutive IOMMU L2 requests to perform when doing sequential invalidation. Regular L2 and invalidation requests will alternate access to the main L2 caches based upon SeqInvBurstLimitInv and SeqInvBurstLimitL2Req.   |
| 7:0   | <b>SeqInvBurstLimitInv.</b> Read-write. Reset: 8h. Sets the number of consecutive invalidation requests to perform when doing sequential invalidation. Regular L2 and invalidation requests will alternate access to the main L2 caches based upon SeqInvBurstLimitInv and SeqInvBurstLimitL2Req. |

### D0F2xF4\_x10 L2\_DTC\_CONTROL

| Bits  | Description                                                                                                                        |
|-------|------------------------------------------------------------------------------------------------------------------------------------|
| 31:28 | <b>DTCEntries.</b> Read-only. Reset: 0. The number of entries in the DTC is indicated as 2^DTCEntries.                             |

**D0F2xF8 IOMMU L1 Config Index**

The index/data pair registers, [D0F2xF8](#) and [D0F2xFC](#) are used to access the registers at [D0F2xFC\\_x\[FFFF:0000\]\\_L1\[3:0\]](#). To access any of these registers, the address is first written into the index

register, [D0F2xF8](#), and then the data is read from or written to the data register, [D0F2xFC](#).

See [2.12.1 \[IOMMU Configuration Space\]](#). There are various L1s in the IOMMU. Registers in the L1 indexed space have one instance per L1 denoted by `_L1i[x]` where `x=D0F2xF8[L1cfgSel]`. The syntax for this register type is described by the following example:

- `D0F2xFC_x00` refers to all instances of the `D0F2xFC_x00` registers.
- `D0F2xFC_x00_L1i[0]` refers to the `D0F2xFC_x00` register instance for the PGD L1.

| 10    | <b>IntDis: interrupt disable.</b> Read-write. 1=INTx interrupt messages generation disabled.                                                                                     |
| 9     | <b>FastB2BEn: fast back-to-back enable.</b> Read-only.                                                                                                                           |
| 8     | <b>SerrEn: System error enable.</b> Read-write. 1=Enables reporting of non-fatal and fatal errors detected.                                                                      |
| 7     | <b>Stepping: Stepping control.</b> Read-only.                                                                                                                                    |
| 6     | <b>ParityErrorEn: parity error response enable.</b> Read-write.                                                                                                                  |
| 5     | <b>PalSnoopEn: VGA palette snoop enable.</b> Read-only.                                                                                                                          |
| 4     | <b>MemWriteInvalidateEn: memory write and invalidate enable.</b> Read-only.                                                                                                      |

|   |                                                                                                                                                   |
|---|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 3 | <b>SpecialCycleEn: special cycle enable.</b> Read-only.                                                                                           |
| 2 | <b>BusMasterEn: bus master enable.</b> Read-write. 1=Memory and IO read and write request generation enabled.                                     |
| 1 | <b>MemAccessEn: IO access enable.</b> Read-write. This bit controls if memory accesses targeting this device are accepted. 1=Enabled. 0=Disabled. |
| 0 | <b>IoAccessEn: IO access enable.</b> Read-write. This bit controls if IO accesses targeting this device are accepted. 1=Enabled. 0=Disabled.      |

### D1F0x08 Class Code/Revision ID Register

| Bits | Description                                         |
|------|-----------------------------------------------------|
| 31:8 | <b>ClassCode.</b> Value: 03_0000h.                  |
| 7:0  | <b>RevID: revision ID.</b> Value: Product-specific. |

### D1F0x0C Header Type Register

Reset: 0080\_0000h.

| Bits  | Description                                                                                                                |
|-------|----------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>BIST.</b> Read-only.                                                                                                    |
| 23:16 | <b>HeaderTypeReg.</b> Read-only. The header type field indicates a header type 0 and that this is a multi-function device. |
| 15:8  | <b>LatencyTimer.</b> Read-only. These bits are fixed at their default value.                                               |
| 7:0   | <b>CacheLineSize.</b> Read-write. This field specifies the system cache line size in units of double words.                |

### D1F0x10 Graphic Memory Base Address

IF (D0F0xD4\_x0109\_14E2[StrapBifF064BarDisA]==1) THEN Reset: 0000\_0008h. ELSE Reset: 0000\_000Ch. ENDIF.

| Bits  | Description                                                                                                                                                                                                                                                                             |      |             |     |            |     |          |     |            |     |          |

| 6     | <b>ParityErrorEn: parity error response enable.</b> Read-write.                                                                                                                  |
| 5     | <b>PalSnoopEn: VGA palette snoop enable.</b> Read-only.                                                                                                                          |

|   |                                                                                                                                                   |
|---|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 4 | <b>MemWriteInvalidateEn: memory write and invalidate enable.</b> Read-only.                                                                       |
| 3 | <b>SpecialCycleEn: special cycle enable.</b> Read-only.                                                                                           |
| 2 | <b>BusMasterEn: bus master enable.</b> Read-write. 1=Memory and IO read and write request generation enabled.                                     |
| 1 | <b>MemAccessEn: IO access enable.</b> Read-write. This bit controls if memory accesses targeting this device are accepted. 1=Enabled. 0=Disabled. |
| 0 | <b>IoAccessEn: IO access enable.</b> Read-write. This bit controls if IO accesses targeting this device are accepted. 1=Enabled. 0=Disabled.      |

#### D1F1x08 Class Code/Revision ID

Reset: 0403\_0000h.

| Bits | Description                           |
|------|---------------------------------------|
| 31:8 | <b>ClassCode.</b> Read-only.          |
| 7:0  | <b>RevID: revision ID.</b> Read-only. |

#### D1F1x0C Header Type

Reset: 0080\_0000h.

| Bits  | Description                                                                                                 |
|-------|-------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>BIST.</b> Read-only. These bits are fixed at their default values.                                       |
| 23:16 | <b>HeaderTypeReg.</b> Read-only. 80h=Type 0 multi-function device.                                          |
| 15:8  | <b>LatencyTimer.</b> Read-only. These bits are fixed at their default value.                                |
| 7:0   | <b>CacheLineSize.</b> Read-write. This field specifies the system cache line size in units of double words. |

#### D1F1x10 Audio Registers Base Address

Reset: 0000\_0000h.

| Bits  | Description                                                                           |
|-------|---------------------------------------------------------------------------------------|
| 31:14 | <b>BaseAddr: base address.</b> Read-write.                                            |
| 13:4  | Reserved.                                                                             |
| 3     | <b>Pref: prefetchable.</b> Read-only. 0=Non-prefetchable memory region.               |
| 2:1   | <b>Type: base address register type.</b> Read-only. 00b=32-bit base address register. |
| 0     | <b>MemSpace: memory space type.</b> Read-only. 0=Memory mapped base address.          |

#### D1F1x14 Base Address 1

Reset: 0000\_0000h.

| Bits | Description |
|------|-------------|
| 31:0 | Reserved.   |

**D1F1x18 Base Address 2**

Reset: 0000\_0000h.

| Bits | Description |

| 31:0 | Reserved.   |

**D1F1x1C Base Address 3**

Reset: 0000\_0000h.

| Bits | Description |
|------|-------------|
| 31:0 | Reserved.   |

**D1F1x20 Base Address 4**

Reset: 0000\_0000h.

| Bits | Description |
|------|-------------|
| 31:0 | Reserved.   |

**D1F1x24 Base Address 5**

Reset: 0000\_0000h.

| Bits | Description |
|------|-------------|
| 31:0 | Reserved.   |

**D1F1x2C Subsystem and Subvendor ID**Reset: 0000\_0000h. This register can be modified through [D1F1x4C](#).

| Bits  | Description                           |
|-------|---------------------------------------|
| 31:16 | <b>SubsystemID</b> . Read-only.       |
| 15:0  | <b>SubsystemVendorID</b> . Read-only. |

**D1F1x30 Expansion ROM Base Address**

Reset: 0000\_0000h.

| Bits | Description |
|------|-------------|
| 31:0 | Reserved.   |

**D1F1x34 Capabilities Pointer**

Reset: 0000\_0050h.

| Bits | Description                                                               |
|------|---------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                 |
| 7:0  | <b>CapPtr: capabilities pointer.</b> Read-only. Pointer to PM capability. |

**D1F1x3C Interrupt Line**

Reset: 0000\_02FFh.

| Bits  | Description                                                                                                          |
|-------|----------------------------------------------------------------------------------------------------------------------|
| 31:16 | Reserved.                                                                                                            |
| 15:8  | <b>InterruptPin: interrupt pin.</b> Read-only. This field identifies the legacy interrupt message the function uses. |
| 7:0   | <b>InterruptLine: interrupt line.</b> Read-write. This field contains the interrupt line routing information.        |

**D1F1x4C Subsystem and Subvendor ID Mirror**

Reset: 0000\_0000h.

| Bits  | Description                                                                                                             |
|-------|-------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>SubsystemID.</b> Read-write. This field sets the value in the corresponding field in <a href="#">D1F1x2C</a> .       |
| 15:0  | <b>SubsystemVendorID.</b> Read-write. This field sets the value in the corresponding field in <a href="#">D1F1x2C</a> . |

**D1F1x50 Power Management Capability**

| Bits  | Description                                                                                                                            |
|-------|----------------------------------------------------------------------------------------------------------------------------------------|
| 31:27 | <b>PmeSupport.</b> Value: 0_0000b. Indicates that there is no PME support.                                                             |
| 26    | <b>D2Support: D2 support.</b> Value: 1. D2 is supported                                                                                |
| 25    | <b>D1Support: D1 support.</b> Value: 1. D1 is supported                                                                                |
| 24:22 | <b>AuxCurrent: auxiliary current.</b> Value: 0.                                                                                        |
| 21    | <b>DevSpecificInit: device specific initialization.</b> Value: 0. Indicates that there is no device specific initialization necessary. |
| 20    | Reserved.                                                                                                                              |
| 19    | <b>PmeClock.</b> Value: 0.                                                                                                             |
| 18:16 | <b>Version: version.</b> Value: 011b.                                                                                                  |
| 15:8  | <b>NextPtr: next pointer.</b> Value: 00h.                                                                                              |
| 7:0   | <b>CapID: capability ID.</b> Value: 01h. Indicates that the capability structure is a PCI power management data structure.             |

**D1F1x54 Power Management Control and Status**

Reset: 0000\_0000h.

| Bits     | Description                                                                                                                                                                                                                                                                                                                                                                  |      |            |     |    |          |          |     |       |

| 21    | <b>TransactionsPending:</b> transactions pending. Read-only.                                                                              |
| 20    | <b>AuxPwr:</b> auxiliary power. Read-only.                                                                                                |
| 19    | <b>UsrDetected:</b> unsupported request detected. Read; Write-1-to-clear. 1=Unsupported request received.                                 |
| 18    | <b>FatalErr:</b> fatal error detected. Read; Write-1-to-clear. 1=Fatal error detected.                                                    |
| 17    | <b>NonFatalErr:</b> non-fatal error detected. Read; Write-1-to-clear. 1=Non-fatal error detected.                                         |
| 16    | <b>CorrErr:</b> correctable error detected. Read; Write-1-to-clear. 1=Correctable error detected.                                         |
| 15    | <b>BridgeCfgRetryEn:</b> bridge configuration retry enable. Read-only.                                                                    |
| 14:12 | <b>MaxRequestSize:</b> maximum request size. Read-only. 0=The root port never generates read requests with size exceeding 128 bytes.      |
| 11    | <b>NoSnoopEnable:</b> enable no snoop. Read-write. 1=The device is permitted to set the No Snoop bit in requests.                         |
| 10    | <b>AuxPowerPmEn:</b> auxiliary power PM enable. Read-only. This capability is not implemented.                                            |
| 9     | <b>PhantomFuncEn:</b> phantom functions enable. Read-only. Phantom functions are not supported.                                           |
| 8     | <b>ExtendedTagEn:</b> extended tag enable. Read-write. 1=8-bit tag request tags. 0=5-bit request tag.                                     |
| 7:5   | <b>MaxPayloadSize:</b> maximum supported payload size. Read-only. 000b=Indicates a 128 byte maximum payload size.                         |
| 4     | <b>RelaxedOrdEn:</b> relaxed ordering enable. Read-write. 1=The device is permitted to set the Relaxed Ordering bit.                      |
| 3     | <b>UsrReportEn:</b> unsupported request reporting enable. Read-write. 1=Enables signaling unsupported requests by sending error messages. |
| 2     | <b>FatalErrEn:</b> fatal error reporting enable. Read-write. 1=Enables sending ERR_FATAL message when a fatal error is detected.          |

|   |                                                                                                                                                |
|---|------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | <b>NonFatalErrEn: non-fatal error reporting enable.</b> Read-write. 1=Enables sending ERR_NONFATAL message when a non-fatal error is detected. |
| 0 | <b>CorrErrEn: correctable error reporting enable.</b> Read-write. 1=Enables sending ERR_CORR message when a correctable error is detected.     |

### D1F1x64 Link Capability

| Bits  | Description                                                                                                                |
|-------|----------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>PortNumber: port number.</b> Value: 0. This field indicates the PCI Express port number for the given PCI Express link. |
| 23:22 | Reserved.                                                                                                                  |

### D1F1x68 Link Control and Status

Reset: 0000\_0000h.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                        |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | <b>LinkAutonomousBWStatus: link autonomous bandwidth status.</b> Read-only.                                                                                                                                                                                                                                                                        |
| 30    | <b>LinkBWManagementStatus: link bandwidth management status.</b> Read-only.                                                                                                                                                                                                                                                                        |
| 29    | <b>DLActive: data link layer link active.</b> Read-only. This bit indicates the status of the data link control and management state machine. Reads return a 1 to indicate the DL_Active state, otherwise 0 is returned.                                                                                                                           |
| 28    | <b>SlotClockCfg: slot clock configuration.</b> Read-only. 1=The root port uses the same clock that the platform provides.                                                                                                                                                                                                                          |
| 27    | <b>LinkTraining: link training.</b> Read-only. 1=Indicates that the physical layer link training state machine is in the configuration or recovery state, or that 1b was written to the RetrainLink bit but link training has not yet begun. Hardware clears this bit when the link training state machine exits the configuration/recovery state. |
| 26    | Reserved.                                                                                                                                                                                                                                                                                                                                          |
| 25:20 | <b>NegotiatedLinkWidth: negotiated link width.</b> Read-only. This field indicates the negotiated width of the given PCI Express link.                                                                                                                                                                                                             |

### D[4:2]F[5:1]x68 IO Link Control and Status Register

Reset: 1001\_0000h.

| Bits | Description                                                                                                                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | <b>LinkAutonomousBWStatus: link autonomous bandwidth status.</b> IF (D[4:2]F[5:1]x64[Link-BWNotificationCap]==0) THEN Read-only. ELSE Read-write; updated-by-hardware. ENDIF.                             |
| 30   | <b>LinkBWManagementStatus: link bandwidth management status.</b> IF (D[4:2]F[5:1]x64[Link-BWNotificationCap]==0) THEN Read-only. ELSE Read-write; updated-by-hardware. ENDIF.                             |
| 29   | <b>DLActive: data link layer link active.</b> Read-only; updated-by-hardware. This bit indicates the status of the data link control and management state machine. 1=DL_Active state. 0=All other states. |
| 28   | <b>SlotClockCfg: slot clock configuration.</b> Read-only; updated-by-hardware. 1=The root port uses the same clock that the platform provides.                                                            |

| 27          | <b>LinkTraining: link training.</b> Read-only; updated-by-hardware. This read-only bit indicates that the physical layer link training state machine is in the configuration or recovery state, or that 1b was written to the RetrainLink bit but link training has not yet begun. Hardware clears this bit when the link training state machine exits the configuration/recovery state.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |                   |     |           |     |          |     |          |     |           |       |           |         |           |     |         |         |           |     |          |         |           |     |          |         |           |     |          |         |           |

| Bits  | Description                                                                                                                                                                                                                                                                                                                             |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:18 | Reserved.                                                                                                                                                                                                                                                                                                                               |
| 17    | <b>PmePending: PME pending.</b> Read-only. This bit indicates that another PME is pending when PmeStatus is set. When PmeStatus is cleared by software; the PME is delivered by hardware by setting the PmeStatus bit again and updating the requestor ID appropriately. PmePending is cleared by hardware if no more PMEs are pending. |
| 16    | <b>PmeStatus: pme status.</b> Read; Write-1-to-clear. This bit indicates that PME was asserted by the requestor ID indicated in the PmeRequestorID field. Subsequent PMEs are kept pending until PmeStatus is cleared by writing a 1.                                                                                                   |
| 15:0  | <b>PmeRequestorId: pme requestor ID.</b> Read-only. This field indicates the PCI requestor ID of the last PME requestor.                                                                                                                                                                                                                |

**D[4:2]F[5:1]x178 Header Log DW3**

Cold reset: 0000\_0000h.

| Bits | Description                                                                                                                                                                                           |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>TlpHdr: transaction layer packet header log.</b> Read-only. Contains the header for a transaction layer packet corresponding to a detected error. The upper byte represents byte 12 of the header. |

**D[4:2]F[5:1]x17C Root Error Command**

Reset: 0000\_0000h.

| Bits | Description                                                                                                                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:3 | Reserved.                                                                                                                                                                                                             |
| 2    | <b>FatalErrRepEn: fatal error reporting enable.</b> Read-write. 1=Enables the generation of an interrupt when a fatal error is reported by any of the devices in the hierarchy associated with this Root Port.        |
| 1    | <b>NonfatalErrRepEn: non-fatal error reporting enable.</b> Read-write. 1=Enables generation of an interrupt when a non-fatal error is reported by any of the devices in the hierarchy associated with this Root Port. |
| 0    | <b>CorrErrRepEn: correctable error reporting enable.</b> Read-write. 1=Enables generation of an interrupt when a correctable error is reported by any of the devices in the hierarchy associated with this Root Port. |

**D[4:2]F[5:1]x180 Root Error Status**

Cold reset: 0000\_0000h.

| Bits  | Description                                                                                                                                                                                     |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:27 | <b>AdvErrIntMsgNum: advanced error interrupt message number.</b> Read-only.                                                                                                                     |
| 26:7  | Reserved.                                                                                                                                                                                       |
| 6     | <b>NFatalErrMsgRcvd: fatal error message received.</b> Read; Write-1-to-clear. Set to 1 when one or more fatal uncorrectable error messages have been received.                                 |
| 5     | <b>NonFatalErrMsgRcvd: non-fatal error message received.</b> Read; Write-1-to-clear. Set to 1 when one or more non-fatal uncorrectable error messages have been received.                       |
| 4     | <b>FirstUncorrFatalRcvd: first uncorrectable fatal error message received.</b> Read; Write-1-to-clear. Set to 1 when the first uncorrectable error message received is for a fatal error.       |
| 3     | <b>MultErrFatalNonfatalRcvd: ERR_FATAL/NONFATAL message received.</b> Read; Write-1-to-clear. Set when either a fatal or a non-fatal error is received and ErrFatalNonfatalRcvd is already set. |
| 2     | <b>ErrFatalNonfatalRcvd: ERR_FATAL/NONFATAL message received.</b> Read; Write-1-to-clear. Set when either a fatal or a non-fatal error is received and this bit is not already set.             |
| 1     | <b>MultErrCorrRcvd: multiple ERR_COR messages received.</b> Read; Write-1-to-clear. Set when a correctable error message is received and ErrCorrRcvd is already set.                            |
| 0     | <b>ErrCorrRcvd: ERR_COR message received.</b> Read; Write-1-to-clear. Set when a correctable error message is received and this bit is not already set.                                         |

### 3.9 Device 18h Function 0 Configuration Registers

See 3.1 [Register Descriptions and Mnemonics]. See 2.7 [Configuration Space].

#### D18F0x00 Device/Vendor ID

| Bits  | Description                                          |
|-------|------------------------------------------------------|
| 31:16 | <b>DeviceID:</b> device ID. Read-only. Value: 141Ah. |
| 15:0  | <b>VendorID:</b> vendor ID. Read-only. Value: 1022h. |

#### D18F0x04 Status/Command

| Bits  | Description                                                                                                         |
|-------|---------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>Status.</b> Read-only. Value: 0010h. Bit[20] is set to indicate the existence of a PCI-defined capability block. |
| 15:0  | <b>Command.</b> Read-only. Value: 0000h.                                                                            |

#### D18F0x08 Class Code/Revision ID

| Bits | Description                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------|
| 31:8 | <b>ClassCode.</b> Read-only. Value: 060000h. Provides the host bridge class code as defined in the PCI specification. |
| 7:0  | <b>RevID:</b> revision ID. Read-only. Value: 00h.                                                                     |

#### D18F0x0C Header Type

Read-only. Value: 0080\_0000h.

| Bits | Description                                                                                                                                                   |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>HeaderTypeReg.</b> These bits are fixed at their default values. The header type field indicates that there are multiple functions present in this device. |

#### D18F0x34 Capabilities Pointer

| Bits | Description                                                 |
|------|-------------------------------------------------------------|
| 31:8 | Reserved.                                                   |
| 7:0  | <b>CapPtr:</b> capabilities pointer. Read-only. Value: 00h. |

#### D18F0x[5C:40] Routing Table

Reset: 0004\_0201h.

**Table 113: Register Mapping** for D18F0x[5C:40]

| 20    | <b>SeqIdSrcNodeEn: sequence ID source node enable</b> . Read-write. Reset: 0. 1=The source node ID of requests is provided in the SeqID field of the corresponding downstream IO link request packets. This may be useful for debug applications, in order to match downstream packets with their originating node. For normal operation, this bit should be cleared. Correct ordering of requests between different nodes is not ensured when this bit is set. Semaphore sharing between differing nodes may not work properly in systems which are capable of processing IO requests with differing non-zero SeqIds out of request order. |      |             |     |          |     |              |     |              |     |              |
| 19    | <b>ApicExtSpur: APIC extended spurious vector enable</b> . Read-write. Reset: 0. This enables the extended APIC spurious vector functionality; it affects <a href="#">APICF0[Vector]</a> . 0=The lower 4 bits of the spurious vector are read-only 1111b. 1=The lower 4 bits of the spurious vector are writable.                                                                                                                                                                                                                                                                                                                           |      |             |     |          |     |              |     |              |     |              |
| 18    | <b>ApicExtId: APIC extended ID enable</b> . Read-write. Reset: 0. Enables the extended APIC ID functionality. 0=APIC ID is 4 bits. 1=APIC ID is 8 bits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |      |             |     |          |     |              |     |              |     |              |

| 6     | <b>InitDet: CPU initialization command detect.</b> Read-write. Reset: 0. This bit may be used by software to distinguish between an INIT and a warm/cold reset by setting it to a 1 before an initialization event is generated. This bit is cleared by RESET_L but not by an INIT command.                                                                                                                                                                                                                                                                                                                                      |
| 5     | <b>BiosRstDet[0]: BIOS reset detect bit[0].</b> Read-write. Cold reset: 0. BiosRstDet[2:0] = {BiosRstDet[2:1], BiosRstDet[0]}. May be used to distinguish between a reset event generated by the BIOS versus a reset event generated for any other reason by setting one or more of the bits to a 1 before initiating a BIOS-generated reset event.                                                                                                                                                                                                                                                                              |
| 4     | <b>ColdRstDet: cold reset detect.</b> Read-write. Cold reset: 0. This bit may be used to distinguish between a cold versus a warm reset event by setting the bit to a 1 before an initialization event is generated.                                                                                                                                                                                                                                                                                                                                                                                                             |

### D18F0x[E4,C4,A4,84] Link Control

Table 114: Register Mapping for D18F0x[E4,C4,A4,84]

| Register      | Function       |
|---------------|----------------|
| D18F0x84      | ONION Link     |
| D18F0xA4      | ONIONPlus Link |
| D18F0x[E4,C4] | Reserved       |

This register is derived from the link control register defined in the link specification.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 31:16 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 15    | <b>Addr64BitEn: 64-bit address packet enable.</b> Read-write. Cold reset: 0000b. 1=Requests to addresses greater than FF_FFFF_FFFFh are supported by this IO link. 0=Requests to addresses greater than FF_FFFF_FFFFh are master aborted as if the end of chain was reached. BIOS is required to ensure that the link-specification-defined “64 Bit Address Feature” bit in the device on the other side of the link is set prior to setting this bit. For coherent links, this bit is unused. <a href="#">D18F0x68[CHtExtAddrEn]</a> is required to be set if this bit is set for any IO link. The link specification indicates that this bit is cleared by a warm reset; therefore this bit may be in a different state than an IO device on the other side of the link after a warm reset; care should be taken by BIOS to place devices on both sides of the link in the same state after a warm reset, before any packets to the high-order addresses enabled by this bit are generated. |

**D18F0x[F0,D0,B0,90] Link Base Channel Buffer Count**

Read-write; Reset-applied.

Table 116: Register Mapping for D18F0x[F0,D0,B0,90]

| Register      | Function       |
|---------------|----------------|
| D18F0x90      | ONION Link     |
| D18F0xB0      | ONIONPlus Link |
| D18F0x[F0,D0] | Reserved       |

D18F0x[F0,D0,B0,90] and D18F0x[F4,D4,B4,94] specify the *hard-allocated* link flow-control buffer counts in each virtual channel available to the transmitter at the other end of the link; it also provides the *free buffers* that may be used by any of the virtual channels, as needed. Base channel buffers are specified in D18F0x[F0,D0,B0,90]; isochronous buffer counts (if in IFCM) are specified in D18F0x[F4,D4,B4,94]. For all fields that specify buffer counts in D18F0x[F0,D0,B0,90] and D18F0x[F4,D4,B4,94], if the link is ganged, then the number of buffers allocated is 2 times the value of the field; If the link is unganged, then the number of buffers allocated is the value of the field.

The cold or warm reset value is determined by whether the link initializes, whether the link is IO/coherent, whether the link is ganged/unganged, and whether the settings are locked by LockBc. Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use D18F0x6C[RlsLnkFullTokCntImm] for the values in the register to take effect. This is necessary even if the values are unchanged from the default values.

The hard-allocated buffer counts are transmitted to the device at the other end of the link in buffer release messages after link initialization. The remaining buffers are held in the free list (specified by FreeData and FreeCmd) used to optimize buffer usage. When a transaction is received, if a free-list buffer is available, it is used for storage instead of one of the hard allocated buffers; as a result, a buffer release (for one of the hard allocated buffers used by the incoming request) can be immediately sent back to the device at the other end of

the link without waiting for the transaction to be routed beyond the flow-control buffers.

**Table 117: Link Buffer Definitions**

| Term            | Definition                                        |
|-----------------|---------------------------------------------------|
| <b>LpbSize</b>  | Link Packet Command Buffer size.<br>LpbSize = 48. |
| <b>LpbdSize</b> | Link Packet Data Buffer size.<br>LpbdSize = 32.   |
| <b>LcsSize</b>  | Link Command Scheduler size.<br>LcsSize = 48.     |

Buffer allocation rules:

- The total number of command buffers allocated in the base and isochronous registers of a link cannot exceed **LpbSize**:
  - $(D18F0x[B0,90][NpReqCmd] + D18F0x[B0,90][PReq] + D18F0x[B0,90][RspCmd] + D18F0x[B0,90][ProbeCmd] + D18F0x[B0,90][FreeCmd] + D18F0x[B4,94][IsocNpReqCmd] + D18F0x[B4,94][IsocPReq] + D18F0x[B4,94][IsocRspCmd]) \leq LpbSize$ .
- The total number of data buffers allocated in the base and isochronous registers of a link cannot exceed **LpbdSize**:
  - $(D18F0x[B0,90][NpReqData] + D18F0x[B0,90][RspData] + D18F0x[B0,90][PReq] + D18F0x[B0,90][FreeData] + D18F0x[B4,94][IsocPReq] + D18F0x[B4,94][IsocNpReqData] + D18F0x[B4,94][IsocRspData]) \leq LpbdSize$ .
- The total number of hard allocated command buffers cannot exceed **LcsSize**.
  - $(D18F0x[B0,90][ProbeCmd] + D18F0x[B0,90][RspCmd] + D18F0x[B0,90][PReq] + D18F0x[B0,90][NpReqCmd] + D18F0x[B4,94][IsocRspCmd] + D18F0x[B4,94][IsocPReq] + D18F0x[B4,94][IsocNpReqCmd]) \leq LcsSize$ .
- BIOS must set up non-zero counts (and adjust the base channel counts accordingly) prior to enabling **IFCM**.
- If an **IOMMU** is present in the system, **D18F0x[F4,D4,B4,94][IsocNpReqCmd]** must be non-zero for all enabled links.
- If an **IOMMU** is present in the system, **D18F0x[E4,C4,A4,84][IsocEn]** must be enabled for the ONION link.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### D18F0x[11C,118,114,110] Link Clumping Enable

Reset: 0000\_0000h. **D18F0x[11C,118,114,110]** are associated with the whole link if it is ganged or sublink 0 if it is unganged; If the node does not support a link, then the corresponding register addresses become reserved.

Table 120: Register Mapping for **D18F0x[11C,118,114,110]**

| Register      | Function       |
|---------------|----------------|
| D18F0x110     | ONION Link     |
| D18F0x114     | ONIONPlus Link |
| D18F0x11[C:8] | Reserved       |

These registers specify how UnitIDs of upstream non-posted requests may be clumped per the link specification. The processor does not clump requests that it generates in the downstream direction.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 31:1 | <b>ClumpEn.</b> Read-write. Each bit of this register corresponds to a link UnitID number. E.g., bit 2 corresponds to UnitID 02h, etc. 1=The specified UnitID is ordered in the same group as the specified UnitID - 1. For example if this register is programmed to 0000_00C0h, then UnitIDs 7h, 6h, and 5h are all ordered as if they are part of the same UnitID. This is used to allow more than 32 tags to be assigned to a single stream for the purposes of ordering. |

### 3.10 Device 18h Function 1 Configuration Registers

See 3.1 [Register Descriptions and Mnemonics]. See 2.7 [Configuration Space].

#### D18F1x00 Device/Vendor ID

| Bits  | Description                                          |
|-------|------------------------------------------------------|
| 31:16 | <b>DeviceID:</b> device ID. Read-only. Value: 141Bh. |
| 15:0  | <b>VendorID:</b> vendor ID. Read-only. Value: 1022h. |

#### D18F1x08 Class Code/Revision ID

| Bits | Description                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------|
| 31:8 | <b>ClassCode.</b> Read-only. Value: 060000h. Provides the host bridge class code as defined in the PCI specification. |
| 7:0  | <b>RevID:</b> revision ID. Read-only. Value: 00h. Processor revision. 00h=A0.                                         |

#### D18F1x0C Header Type

Reset: 0080\_0000h.

| Bits | Description                                                                                                                                                              |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>HeaderTypeReg.</b> Read-only. These bits are fixed at their default values. The header type field indicates that there are multiple functions present in this device. |

#### D18F1x[17C:140,7C:40] DRAM Base/Limit

The following sets of registers specify the DRAM address ranges:

Table 123: Register Mapping for D18F1x[17C:140,7C:40]

| Function | Base Low                      | Limit Low                     | Base High                       | Limit High                      |
|----------|-------------------------------|-------------------------------|---------------------------------|---------------------------------|
| Range 0  | D18F1x40                      | D18F1x44                      | D18F1x140                       | D18F1x144                       |
| Reserved | D18F1x48,<br>D18F1x[7:5][8,0] | D18F1x4C,<br>D18F1x[7:5][C,4] | D18F1x148,<br>D18F1x1[7:5][8,0] | D18F1x14C,<br>D18F1x1[7:5][C,4] |

Transaction addresses that are within the specified base/limit range are routed to the DstNode. See 2.8.2 [NB Routing].

DRAM mapping rules:

F1x0XX registers provide the low address bits. F1x1XX registers provide the high address bits.

- Transaction addresses are within the defined range if:  
 $\{\text{DramBase}[47:24], 00\_0000h\} \leq \text{address}[47:0] \leq \{\text{DramLimit}[47:24], FF\_FFFFh\}$ .
- DRAM regions must not overlap each other.
- Accesses to addresses that map to both DRAM, as specified by the DRAM base and limit registers (F1x[1, 0][7C:40]), and MMIO, as specified by D18F1x[2CC:2A0,1CC:180,BC:80], are routed to MMIO only.

- Programming of the DRAM address maps must be consistent with the Memory-Type Range Registers (MTRRs) and the top of memory registers, [MSRC001\\_001A](#) and [MSRC001\\_001D](#). CPU accesses only hit within the DRAM address maps if the corresponding MTRR is of type DRAM. Accesses from IO links are routed based on the DRAM base and limit registers (F1x[1, 0][7C:40]) only.
- The appropriate RE or WE bit(s) must be set. When initializing a base/limit pair, the BIOS must write the [limit] register before either the RE or WE bit is set. When changing a base/limit pair that is already enabled, the BIOS should clear RE and WE before changing the address range.
- See [2.8.2.1.1 \[DRAM and MMIO Memory Space\]](#).

When memory hoisting is enabled in a node via [D18F1x2\[1,0\]\[8,0\]\[LgcyMmioHoleEn\]](#), the corresponding BaseAddr/LimitAddr should be configured to account for the memory hoisted above the hole. See [2.9.12 \[Memory Hoisting\]](#).

### D18F1x[7:4][8,0] DRAM Base Low

IF ([D18F2x118\[LockDramCfg\]](#)) THEN Read-only. ELSE Read-write. ENDIF. Reset: 0000\_0000h.

**D18F1x[2CC:2A0,1CC:180,BC:80] MMIO Base/Limit**

These registers, The memory mapped IO base and limit registers D18F1x[2CC:2A0,1CC:180,BC:80] specify the mapping from memory addresses to the corresponding node and IO link for MMIO transactions. Address ranges are specified by upto 16 sets of base/limit registers.

Transaction addresses that are within the specified base/limit range are routed to the node specified by DstNode and the link specified by DstLink. See [2.8.2 \[NB Routing\]](#).

MMIO mapping rules:

- Transaction addresses are within the defined range if:  
 $\{\text{MMIOBase}[47:16], 0000\text{h}\} \leq \text{address}[47:0] \leq \{\text{MMIOLimit}[47:16], \text{FFFFh}\}$ .
- MMIO regions must not overlap each other.
- Accesses to addresses that map to both DRAM, as specified by the DRAM base and limit registers (see [D18F1x\[17C:140,7C:40\]](#)), and MMIO, as specified by the memory mapped IO base and limit registers (F1x[BC:80]), are routed to MMIO only.
- Programming of the MMIO address maps must be consistent with the Memory-Type Range Registers (MTRRs) and the top of memory registers, [MSRC001\\_001A](#) and [MSRC001\\_001D](#). CPU accesses only hit within the MMIO address maps if the corresponding MTRR is of type IO. Accesses from IO links are routed based on [D18F1x\[2CC:2A0,1CC:180,BC:80\]](#).
- The appropriate RE or WE bit(s) must be set. When initializing a base/limit pair, the BIOS must write the limit register before either the RE or WE bit is set. When changing a base/limit pair that is already enabled, the BIOS should clear RE and WE before changing the address range.
- Scenarios in which the address space of multiple MMIO ranges target the same IO device is supported.
- See [2.8.2.1.1 \[DRAM and MMIO Memory Space\]](#).

| 7    | <b>NP: non-posted.</b> Read-write. Reset: 0. 1=CPU write requests to this MMIO range are passed through the non-posted channel. This may be used to force writes to be non-posted for MMIO regions which map to the legacy ISA/LPC bus, or in conjunction with D18F0x68[DsNpReqLmt] in order to allow downstream CPU requests to be counted and thereby limited to a specified number. This latter use of the NP bit may be used to avoid loop deadlock scenarios in systems that implement a region in an IO device that reflects downstream accesses back upstream. See the link summary of deadlock scenarios for more information. 0=CPU writes to this MMIO range use the posted channel. This bit does not affect requests that come from IO links (the virtual channel of the request is specified by the IO request).<br><br>If two MMIO ranges target the same IO device and the NP bit is set differently in both ranges, unexpected transaction ordering effects are possible. In particular, using PCI- and IO-link-defined producer-consumer semantics, if a producer (e.g., the processor) writes data using a non-posted MMIO range followed by a flag to a posted MMIO range, then it is possible for the device to see the flag updated before the data is updated. |      |             |     |        |     |        |     |        |     |        |
| 6    | <b>DstSubLink: destination sublink.</b> Read-write. Reset: 0. When a link is unganged, this bit specifies the destination sublink of the link specified by the memory mapped IO base and limit registers F1x[BC:80][DstLink]. 0=The destination link is sublink 0. 1=The destination link is sublink 1. If the link is ganged, then this bit must be low.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |      |             |     |        |     |        |     |        |     |        |
| 5:4  | <b>DstLink: destination link ID.</b> Read-write. Reset: 0. For transactions within this MMIO range, this field specifies the destination IO link number of the destination node.<br><table> <tr> <th>Bits</th><th>Description</th></tr> <tr> <td>00b</td><td>Link 0</td></tr> <tr> <td>01b</td><td>Link 1</td></tr> <tr> <td>10b</td><td>Link 2</td></tr> <tr> <td>11b</td><td>Link 3</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Bits | Description | 00b | Link 0 | 01b | Link 1 | 10b | Link 2 | 11b | Link 3 |

### **D18F1x[DC:C0] IO-Space Base/Limit**

The IO-space base and limit registers, [D18F1x\[DC:C0\]](#), specify the mapping from IO addresses to the corresponding node and IO link for transactions resulting from x86-defined IN and OUT instructions. IO address ranges are specified by upto 8 sets of base/limit registers. The first set is F1xC0 and F1xC4, the second set is F1xC8 and F1xCC, and so forth. Transaction addresses that are within the specified base/limit range are routed to the node specified by DstNode and the link specified by DstLink. See [2.8.2 \[NB Routing\]](#).

IO mapping rules:

- IO-space transaction addresses are within the defined range if:  
{IOBase[24:12], 000h} <= address <= {IOLimit[24:12], FFFh} and as specified by the IE bit; or  
if the address is in the range specified by the VE bits.
- IO regions must not overlap each other.
- The appropriate RE or WE bit(s) must be set.
- See [2.8.2.1.2 \[IO Space\]](#).

### **D18F1x[1F:1E,D:C][8,0] IO-Space Base**

| 5     | <b>IE: ISA enable.</b> Read-write. Reset: 0. 1=The IO-space address window is limited to the first 256 B of each 1 KB block specified; this only applies to the first 64 KB of IO space. 0=The PCI IO window is not limited in this way.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 4     | <b>VE: VGA enable.</b> Read-write. Reset: 0. 1=Include IO-space transactions targeting the VGA-compatible address space within the IO-space window of this base/limit pair. These include IO accesses in which address bits[9:0] range from 3B0h to 3BBh or 3C0h to 3DFh (address bits[15:10] are not decoded); this only applies to the first 64 KB of IO space; i.e., address bits[24:16] must be low). 0=IO-space transactions targeting VGA-compatible address ranges are not added to the IO-space window. This bit should only ever be set in one register. The MMIO range associated with the VGA enable bit in the PCI specification is NOT included in the VE bit definition; to map this range to an IO link, see <a href="#">D18F1xF4 [VGA Enable]</a> . When <a href="#">D18F1xF4[VE]</a> is set, the state of this bit is ignored. |

### D18F1x[1DC:1D0,EC:E0] Configuration Map

**D18F1x[1DC:1D0,EC:E0]** specify the mapping from configuration address to the corresponding node and IO link. Configuration address ranges are specified by upto 8 pairs of base/limit registers. Transaction addresses that are within the specified base/limit range are routed to the node specified by DstNode and the link specified by DstLink. See 2.8.2 [NB Routing].

Table 134: Register Mapping for D18F1x[1DC:1D0,EC:E0]

| Register       | Function |
|----------------|----------|
| D18F1xE0       | Range 0  |
| D18F1xE4       | Range 1  |
| D18F1xE8       | Range 2  |
| D18F1xEC       | Range 3  |
| D18F1x1[DC:D0] | Reserved |

Configuration space mapping rules:

- Configuration addresses (to “BusNo” and “Device” as specified by [IOCF8 \[IO-Space Configuration Address\]](#) in the case of IO accesses or [2.7 \[Configuration Space\]](#) in the case of MMIO accesses) are within the defined range if:  
 $(\{BusNumBase[7:0]\} \leq BusNo \leq \{BusNumLimit[7:0]\}) \& (DevCmpEn==0);$  or  
 $(\{BusNumBase[4:0]\} \leq Device \leq \{BusNumLimit[4:0]\}) \& (DevCmpEn==1) \& (BusNo == 00h).$
- Configuration regions must not overlap each other.
- The appropriate RE or WE bit(s) must be set.
- See 2.8.2.1.3 [Configuration Space].

| Bits  | Description                                                                                                                                                                                     |

| 0   | <b>VE: VGA enable.</b> Read-write. 1=Transactions targeting the VGA-compatible address space are routed and controlled as specified by this register. The VGA-compatible address space is: (1) the MMIO range <a href="#">A_0000h</a> through <a href="#">B_FFFFh</a> ; (2) IO-space accesses in which address bits[9:0] range from <a href="#">3B0h</a> to <a href="#">3BBh</a> or <a href="#">3C0h</a> to <a href="#">3DFh</a> (address bits[15:10] are not decoded; this only applies to the first 64 KB of IO space; i.e., address bits[24:16] must be low). 0=Transactions targeting the VGA-compatible address space are not affected by the state of this register. When this bit is set, the state of <a href="#">D18F1xF4[VE]</a> is ignored. |

### D18F1x10C DCT Configuration Select

### D18F1x120 DRAM Base System Address

IF ([D18F2x118\[LockDramCfg\]](#)) THEN Read-only. ELSE Read-write. ENDIF. Cold reset: 0000\_0000h.

[D18F1x120](#) and [D18F1x124](#) are required to specify the base and limit system address range of the DRAM connected to the local node.

DRAM accesses to the local node with physical address Addr[47:0] that are within the following range are directed to the DCTs:

{DramBaseAddr[47:27], 000\_0000h} <= Addr[47:0] <= {DramLimitAddr[47:27], 7FF\_FFFFh};

DRAM accesses to the local node that are outside of this range are master aborted.

The address of the DRAM transaction is normalized before passing it to the DCTs by subtracting DramBaseAddr.

This range is also used to specify the range of DRAM covered by the scrubber (see [D18F3x58](#) and [D18F3x5C](#)).

| Bits  | Description                 |
|-------|-----------------------------|
| 31:21 | Reserved.                   |
| 20:0  | <b>DramBaseAddr[47:27].</b> |

### D18F1x124 DRAM Limit System Address

IF ([D18F2x118\[LockDramCfg\]](#)) THEN Read-only. ELSE Read-write. ENDIF. See [D18F1x120 \[DRAM Base System Address\]](#).

| Bits  | Description                                        |
|-------|----------------------------------------------------|
| 31:24 | Reserved                                           |
| 23:21 | Reserved.                                          |
| 20:0  | <b>DramLimitAddr[47:27].</b> Cold reset: 1F_FFFFh. |

**D18F1x2[1C:00] DRAM Controller Base/Limit**

The DRAM controller base and limit registers define a DRAM controller address range and specify the mapping of physical DRAM addresses to a DCT as selected by DctSel or DctIntLvEn. The following base/limit register pairs specify the address ranges:

Table 135: [Register Mapping](#) for D18F1x2[1C:00]

| Function | Base Address | Limit Address |
|----------|--------------|---------------|
| Range 0  | D18F1x200    | D18F1x204     |
| Range 1  | D18F1x208    | D18F1x20C     |
| Range 2  | D18F1x210    | D18F1x214     |
| Range 3  | D18F1x218    | D18F1x21C     |

BIOS should observe the following DCT configuration requirements:

- DRAM addresses are within the defined range if:  
 $\{\text{DctBaseAddr}[47:27], 000b, 00\_0000h\} \leq \text{address}[47:0] \leq \{\text{DctLimitAddr}[47:27], 111b, FF\_FFFFh\}$ .
- DCT base/limit address ranges must not overlap each other.
- A maximum of two address ranges may be mapped to a single DCT.

**Hoisting.** When memory hoisting is enabled via LegacyMmioHoleEn, the corresponding DctBaseAddr/DctLimitAddr should be configured to account for the memory hoisted above the hole. A contiguous memory hole should only be mapped by one DctBaseAddr/DctLimitAddr pair. See [2.9.12 \[Memory Hoisting\]](#).

**Channel interleaving.** A DRAM address range may be mapped to one DCT as a continuous region, or it may be interleaved between DCTs. See [2.9.11.2 \[Channel Interleaving\]](#).

**D18F1x2[1,0][8,0] DRAM Controller Base**

IF (D18F2x118[LockDramCfg]) THEN Read-only. ELSE Read-write. ENDIF. Reset: 0000\_0000h.

Table 136: [Register Mapping](#) for D18F1x2[1,0][8,0]

| Register  | Function |
|-----------|----------|
| D18F1x200 | Range 0  |
| D18F1x208 | Range 1  |
| D18F1x210 | Range 2  |

#### D18F2x[5C:40]\_dct[3:0] DRAM CS Base Address

See 2.9.3 [DCT Configuration Registers].

These registers along with D18F2x[6C:60]\_dct[3:0] [DRAM CS Mask], translate DRAM request addresses (to a DRAM controller) into DRAM chip selects. Supported DIMM sizes are specified in D18F2x80\_dct[3:0] [DRAM Bank Address Mapping]. For more information on the DRAM controllers, see 2.9 [DRAM Controllers (DCTs)].

For each chip select, there is a DRAM CS Base Address register. For each CS pair there is a DRAM CS Mask Register. For each CS pair, an even CS must be populated if the odd CS is populated. If a chipselect is populated in the system it must be indicated to the DCT by setting one of the mutually exclusive {CSEnable, TestFail} configuration bits.

**Table 139: DIMM, Chip Select, and Register Mapping**

| Base Address Registers | Mask Register | Logical DIMM | Chip Select <sup>1</sup> |
|------------------------|---------------|--------------|--------------------------|
| D18F2x40_dct[x]        | F2x60         | 0            | MEMCS[x]_L[0]            |
| D18F2x44_dct[x]        |               |              | MEMCS[x]_L[1]            |

**Table 139: DIMM, Chip Select, and Register Mapping**

| Base Address Registers                          | Mask Register | Logical DIMM | Chip Select <sup>1</sup> |
|-------------------------------------------------|---------------|--------------|--------------------------|

| D18F2x[5C:50]_dct[x]                            | F2x6[C,8]     | Reserved     |                          |
| 1. See 2.9.4 [DDR Pad to Processor Pin Mapping] |               |              |                          |

The DRAM controller operates on the normalized physical address of the DRAM request. The normalized physical address includes all of the address bits that are supported by a DRAM controller. See 2.8 [Northbridge (NB)].

Each base address register specifies the starting normalized address of the block of memory associated with the chip select. Each mask register specifies the additional address bits that are consumed by the block of memory associated with the chip selects. If both chip selects of a DIMM are used, they must be the same size; in this case, a single mask register covers the address space consumed by both chip selects.

Lower-order address bits are provided in the base address and mask registers, as well. These allow memory to be interleaved between chip selects, such that contiguous physical addresses map to the same DRAM page of multiple chip selects. See 2.9.11.1 [Chip Select Interleaving]. The hardware supports the use of lower-order address bits to interleave chip selects if (1) the each chip select of the memory system spans the same amount of memory and (2) the number of chip selects of the memory system is a power of two.

BIOS is required to assign the largest DIMM chip-select range to the lowest normalized address of the DRAM controller. As addresses increase, the chip-select size is required to remain constant or decrease. This is necessary to keep DIMM chip-select banks on aligned address boundaries, regardless as to the amount of address space covered by each chip select.

For each normalized address for requests that enters a DRAM controller, a ChipSelect[i] is asserted if:

### D18F2x7C\_dct[3:0] DRAM Initialization

Reset: 0000\_0000h. See [2.9.3 \[DCT Configuration Registers\]](#).

For [Ddr3Mode](#), BIOS can directly control the DRAM initialization sequence using this register. To do so, BIOS sets EnDramInit to start DRAM initialization. BIOS should then complete the initialization sequence specified in the appropriate JEDEC specification. After completing the sequence, BIOS clears EnDramInit to complete DRAM initialization. BIOS should not assert LDTSTOP\_L while EnDramInit is set. Setting more than one of the command bits in this register (SendControlWord, SendMrsCmd, and SendAutoRefresh) at a time results in undefined behavior.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |      |             |     |                            |     |                            |     |                            |     |                            |

| 23                            | <p><b>PchgPDMoSel: precharge power down mode select.</b> Read-write. BIOS: 1. Specifies how a chip select enters and exits power down mode. This mode is enabled by <a href="#">D18F2x94_dct[3:0][PowerDownEn]</a> and its behavior varies based on the setting of <a href="#">D18F2x94_dct[3:0][PowerDownMode]</a> and <a href="#">MR0[PPD]</a> in <a href="#">D18F2x2E8_dct[3:0]_mp[1:0][MxMr0]</a>.</p> <table><tr><th><a href="#">PowerDownMode</a></th><th><a href="#">PchgPDMoSel</a></th><th><a href="#">MR0[PPD]</a></th><th>Description</th></tr><tr><td>0b</td><td>0b</td><td>0b</td><td>Full channel slow exit (DLL off)</td></tr><tr><td>0b</td><td>0b</td><td>1b</td><td>Full channel fast exit (DLL on)</td></tr><tr><td>0b</td><td>1b</td><td>xb</td><td>Full channel dynamic fast exit/slow exit</td></tr><tr><td>1b</td><td>0b</td><td>0b</td><td>Reserved</td></tr><tr><td>1b</td><td>0b</td><td>1b</td><td>Partial channel fast exit (DLL on)</td></tr><tr><td>1b</td><td>1b</td><td>xb</td><td>Partial channel dynamic fast exit/slow exit</td></tr></table> <p>See <a href="#">D18F2x248_dct[3:0]_mp[1:0][Txpdll, Txp]</a>. In dynamic fast exit/slow exit power down mode, the DCT dynamically issues MRS command(s) to the DRAM to specify the powerdown mode; the DCT specifies fast exit mode when chip selects on one of the CKEs has recently been active; it specifies deep power down when chip selects on all CKEs have been idle. PchgPDMoSel=0 &amp;&amp; MR0[PPD]=1 fast exit modes are reserved if S3 is also supported .</p> | <a href="#">PowerDownMode</a> | <a href="#">PchgPDMoSel</a>                 | <a href="#">MR0[PPD]</a> | Description | 0b  | 0b                   | 0b      | Full channel slow exit (DLL off) | 0b | 0b | 1b | Full channel fast exit (DLL on) | 0b | 1b | xb | Full channel dynamic fast exit/slow exit | 1b | 0b | 0b | Reserved | 1b | 0b | 1b | Partial channel fast exit (DLL on) | 1b | 1b | xb | Partial channel dynamic fast exit/slow exit |

| 1:0                           | <p><b>BurstCtrl: burst length control.</b> Read-write. BIOS: 01b. Specifies the number of sequential beats of DQ related to one read or write command. Requests from the processor are always 64-byte-length. Requests generated by <a href="#">D18F2x250_dct[3:0]</a> are always 64-byte-length. Requests from GMC may be 32-byte or 64-byte-length. Software must ensure that GMC requests are disabled to configure the controller and drams for 8-beat burst length (e.g. during training). If this mode is changed, software must issue a mode-register set command to MR0 of the drams to place them in the same mode.</p> <table><tr><th><a href="#">Bits</a></th><th><a href="#">Description</a></th></tr><tr><td>00b</td><td>8 beats</td></tr><tr><td>01b</td><td>Dynamic 4 or 8 beats</td></tr><tr><td>11b-10b</td><td>Reserved</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | <a href="#">Bits</a>          | <a href="#">Description</a>                 | 00b                      | 8 beats     | 01b | Dynamic 4 or 8 beats | 11b-10b | Reserved                         |    |    |    |                                 |    |    |    |                                          |    |    |    |          |    |    |    |                                    |    |    |    |                                             |
